### Definition

02

## Introduction to Boolean Algebra

- 2.1: History and Meaning
- 2.2: Recap on Prescedence
- 2.3: Conjunction
- 2.4: Disjunction
- 2.5: Negation

03

## Decision Control Structures

- 3.1: Definition
- 3.2: 'if' Statement
- 3.3: 'if ... else' Statement
- 3.4: 'if ... elif' Statement
- 3.5: 'if...elif...else' Statement
- 3.6: 'Match-Case' Statement

04

## Nesting

# Definition

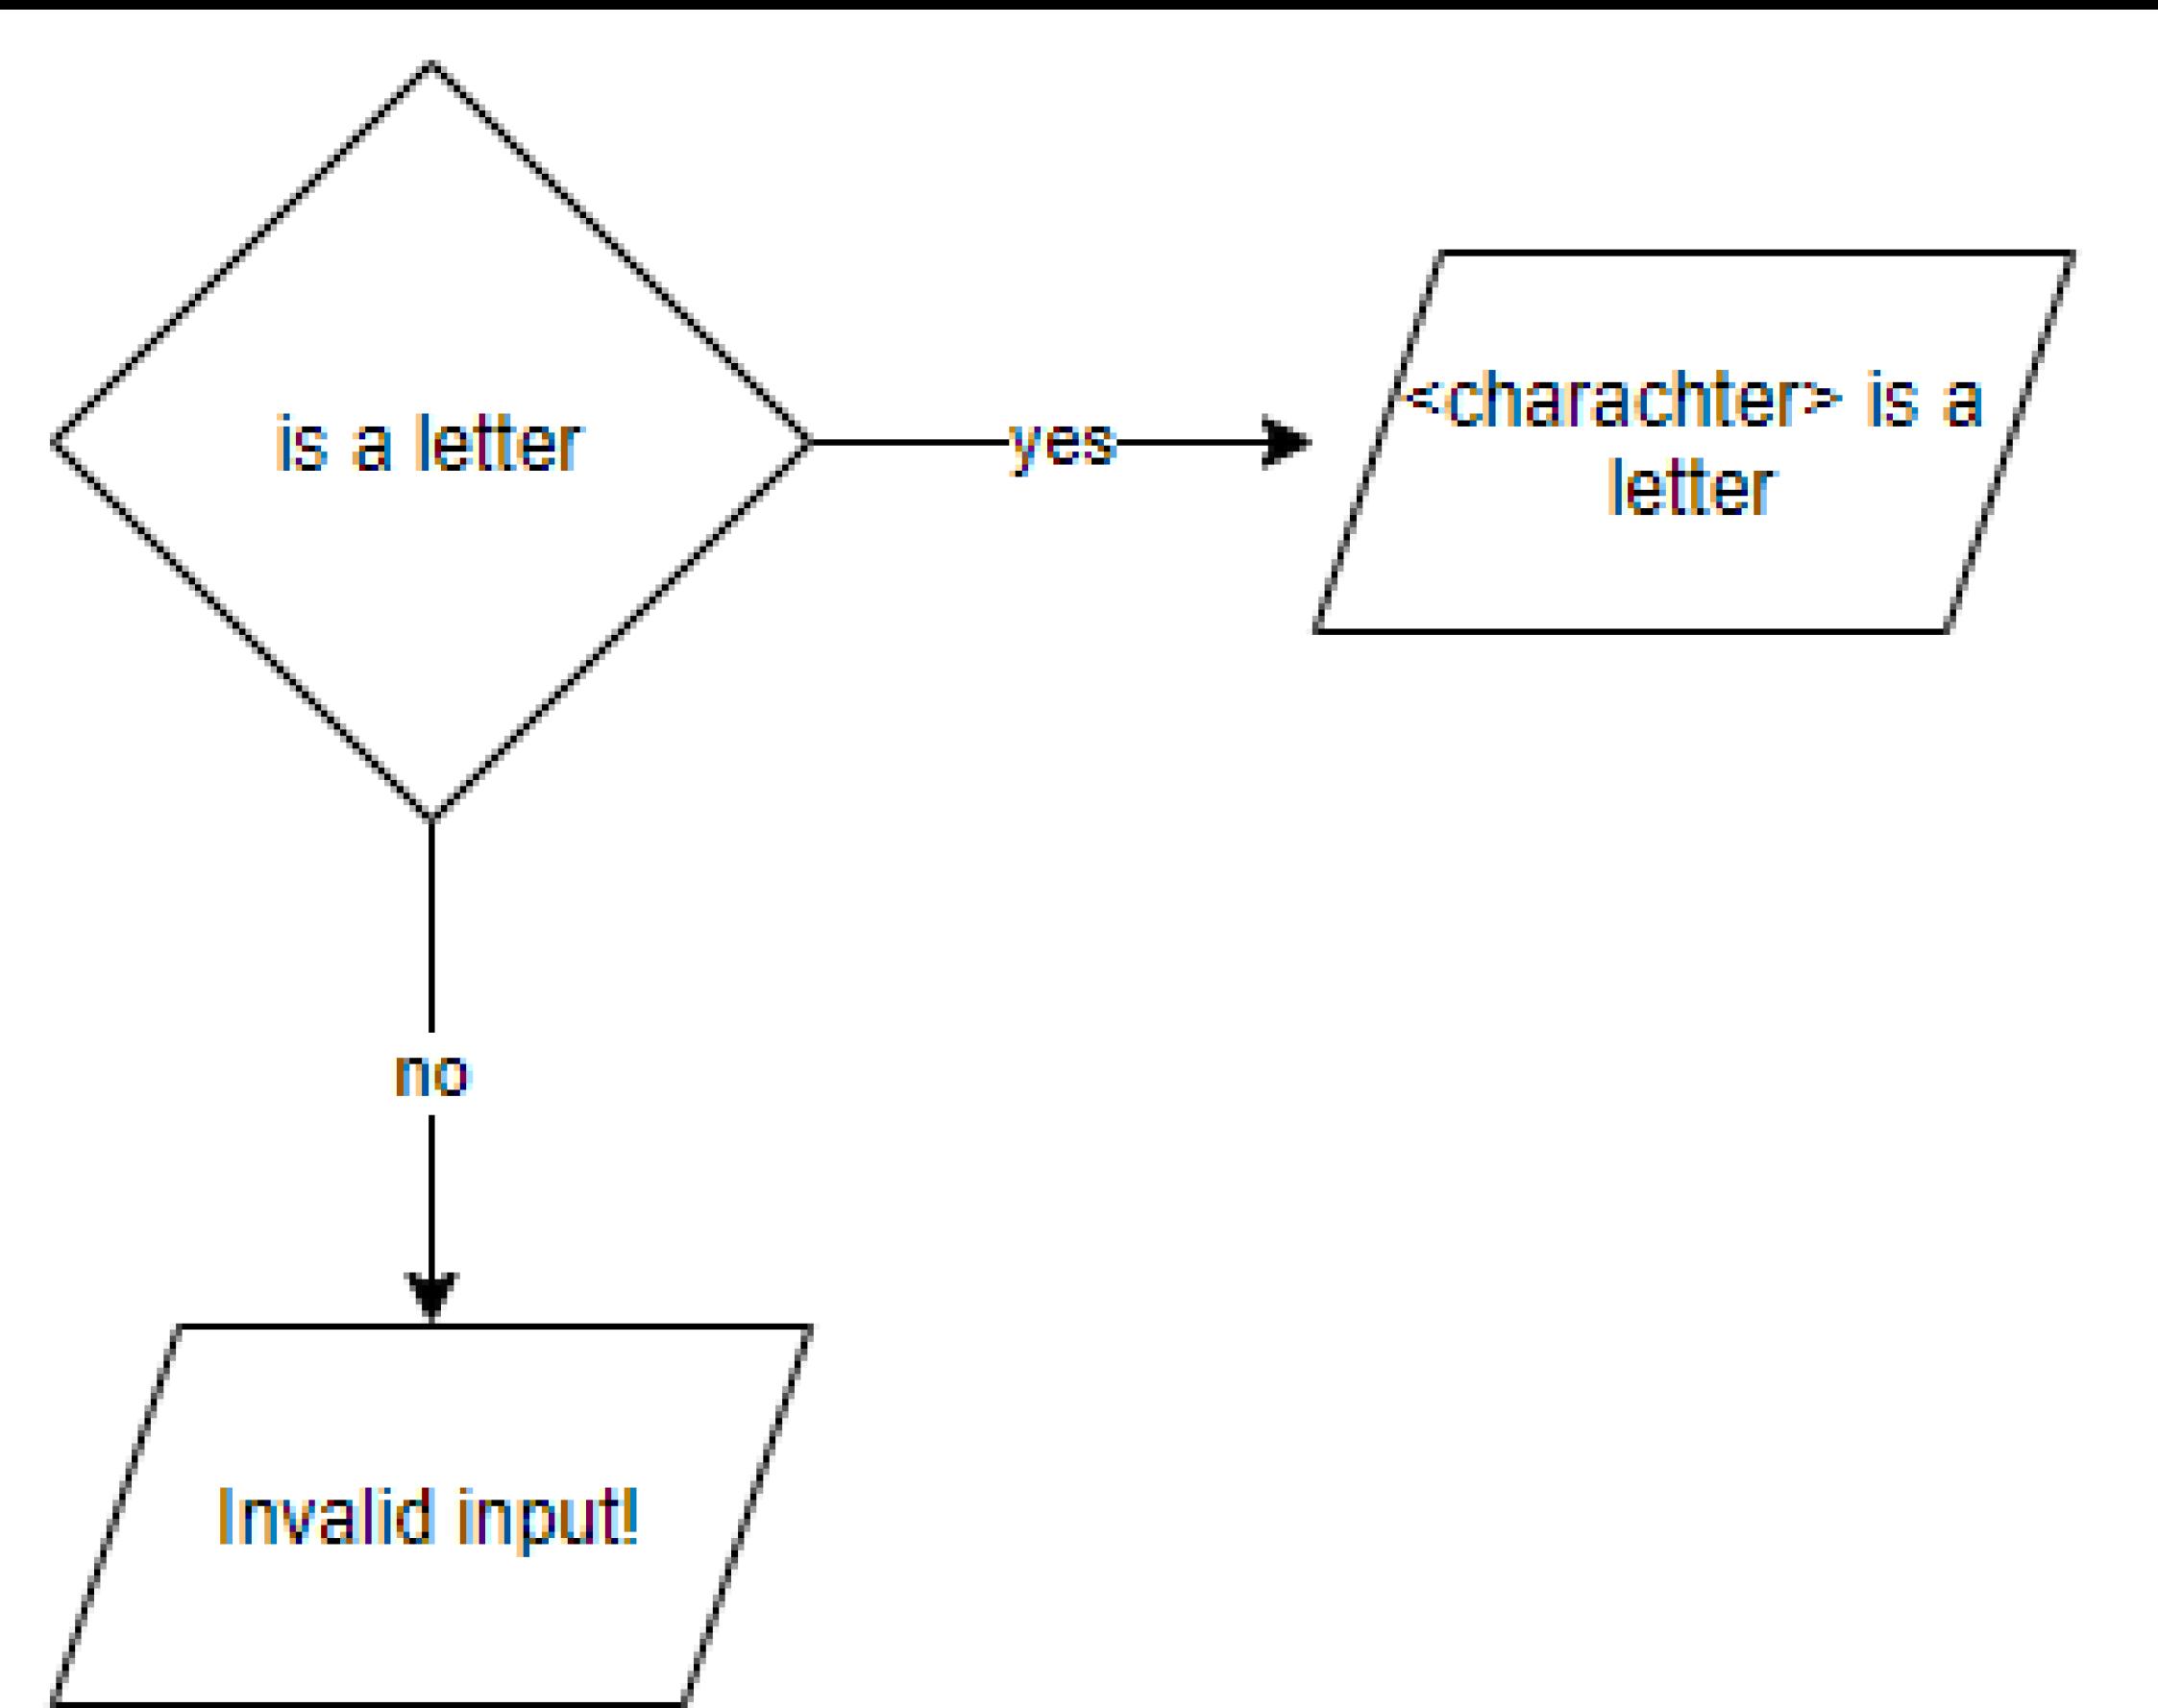

- A condition is something that a computer can decide is either true or false. True is like the computer is answering yes and false is like answering no. You can tell your app to do different things depending on if the condition is true or false.

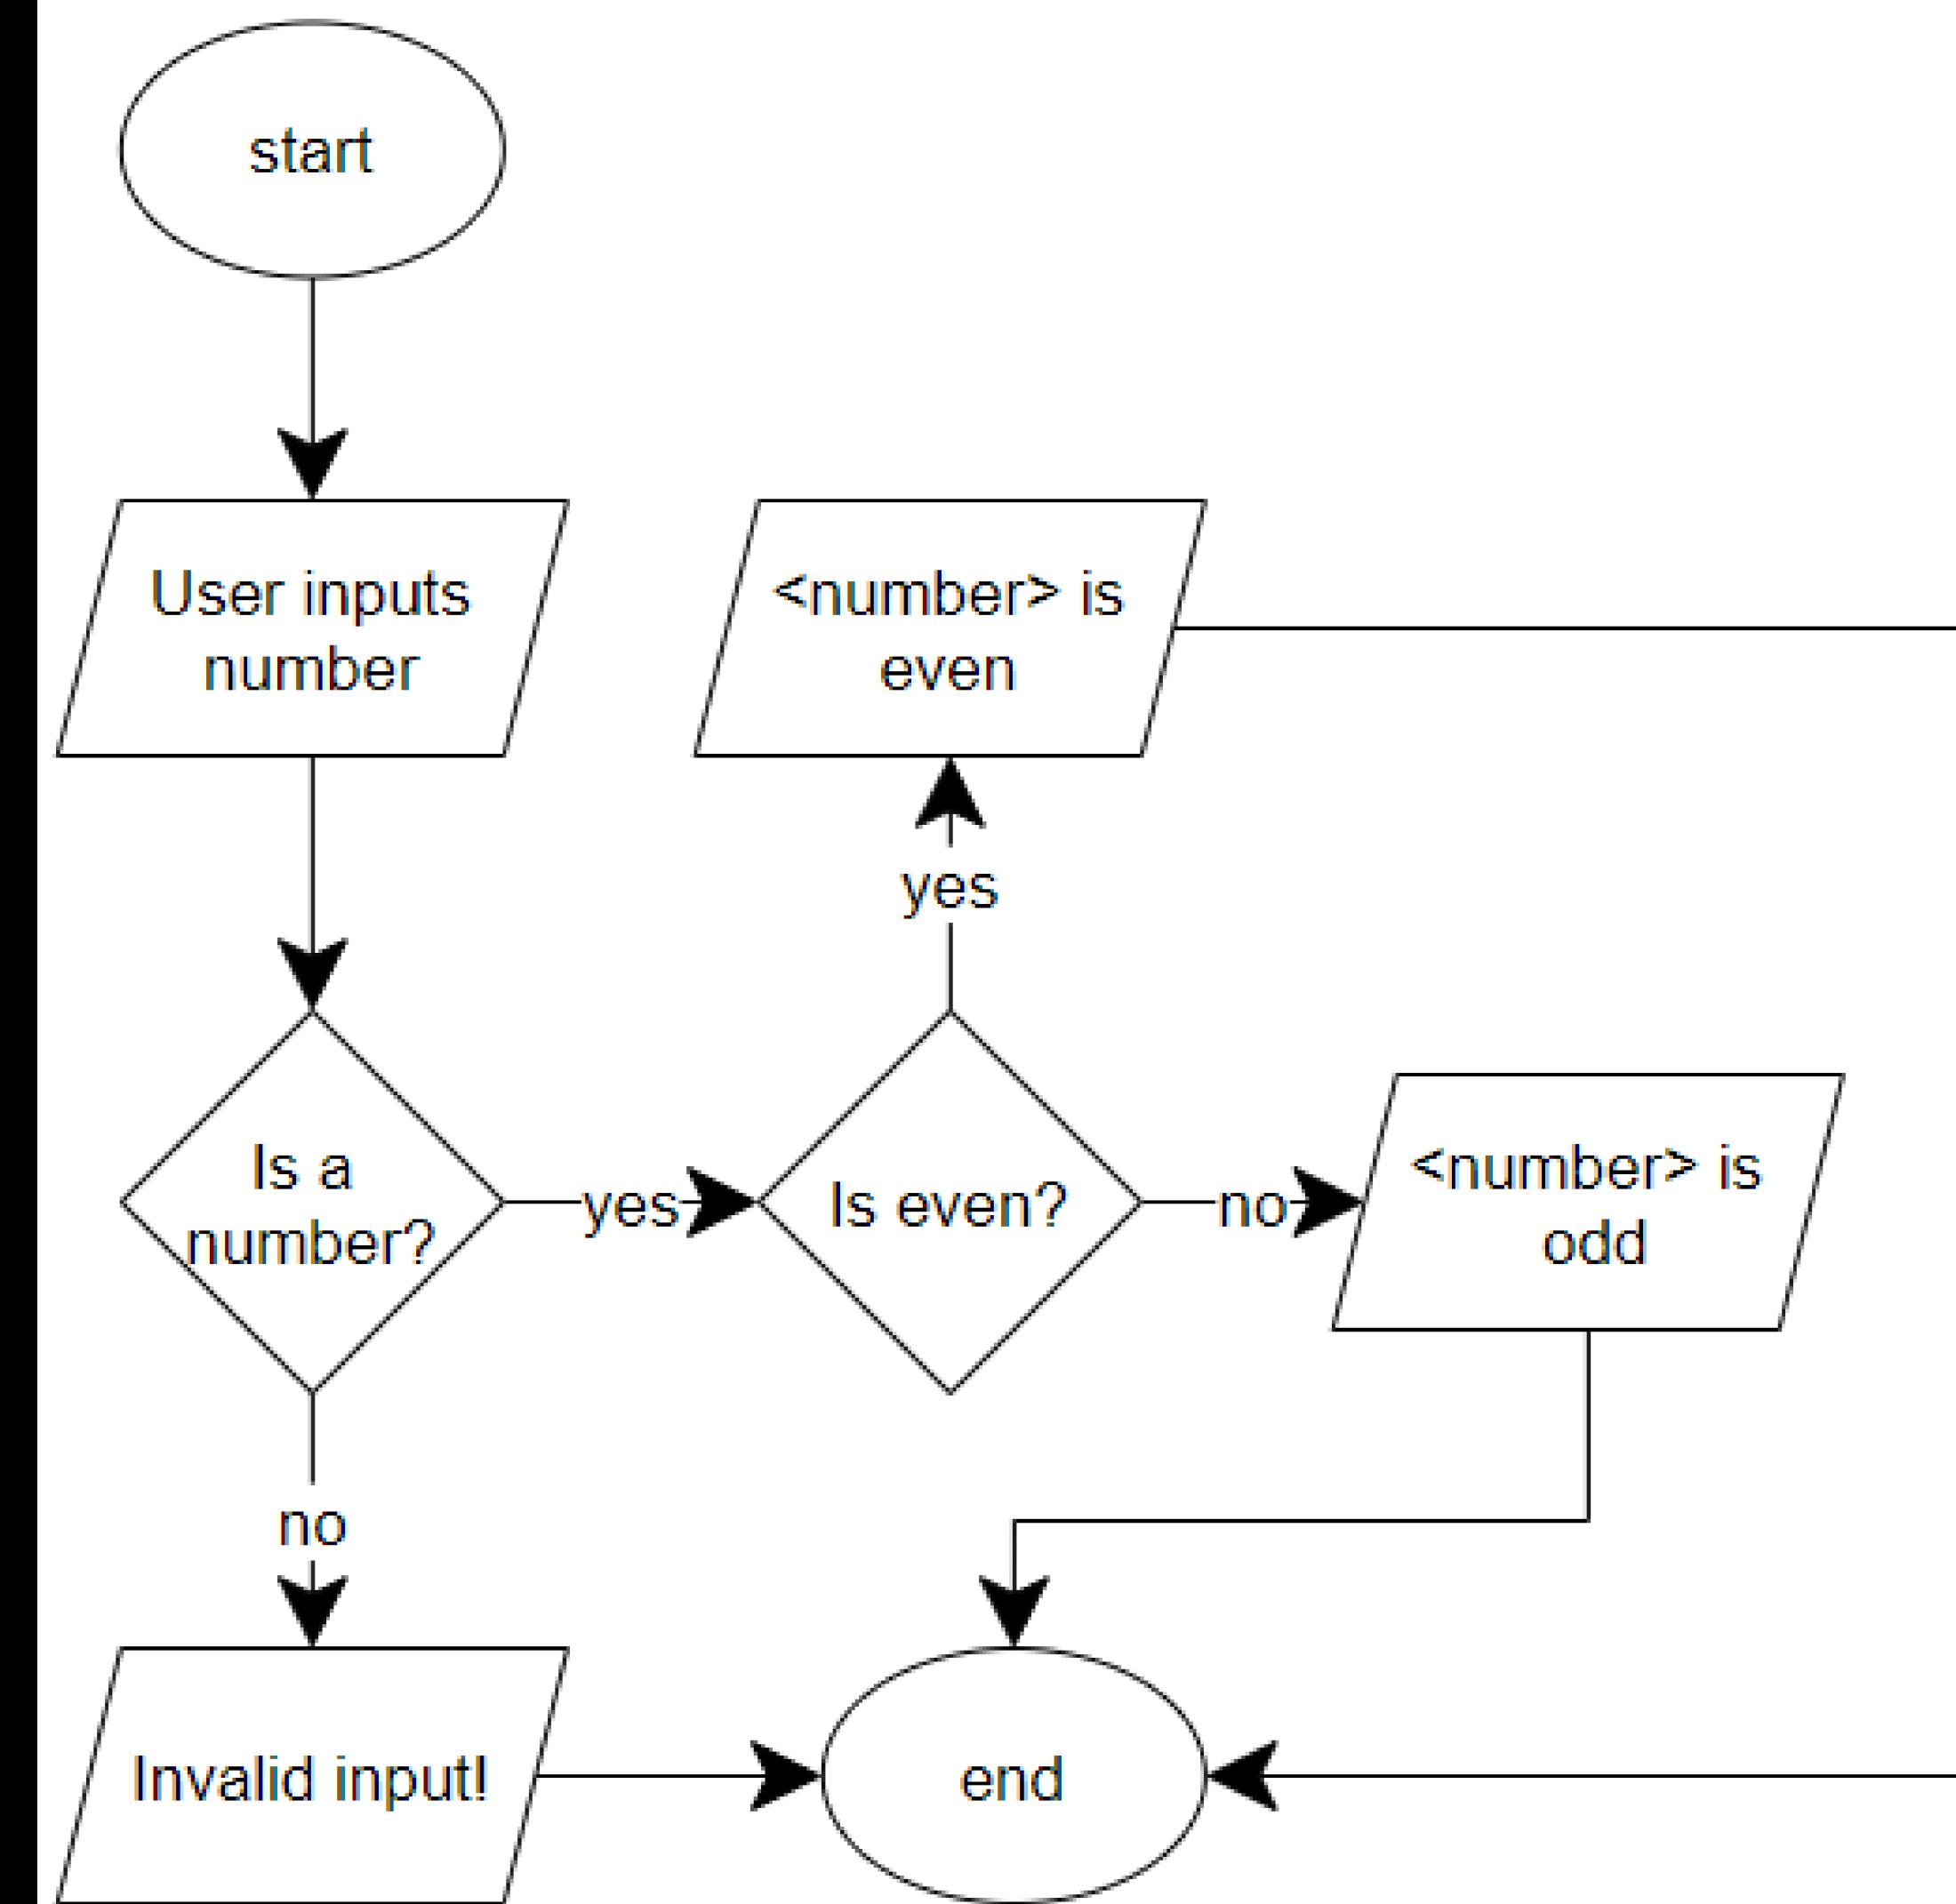

# Definition

- These are branches of the algorithm, the logic of where your code is going

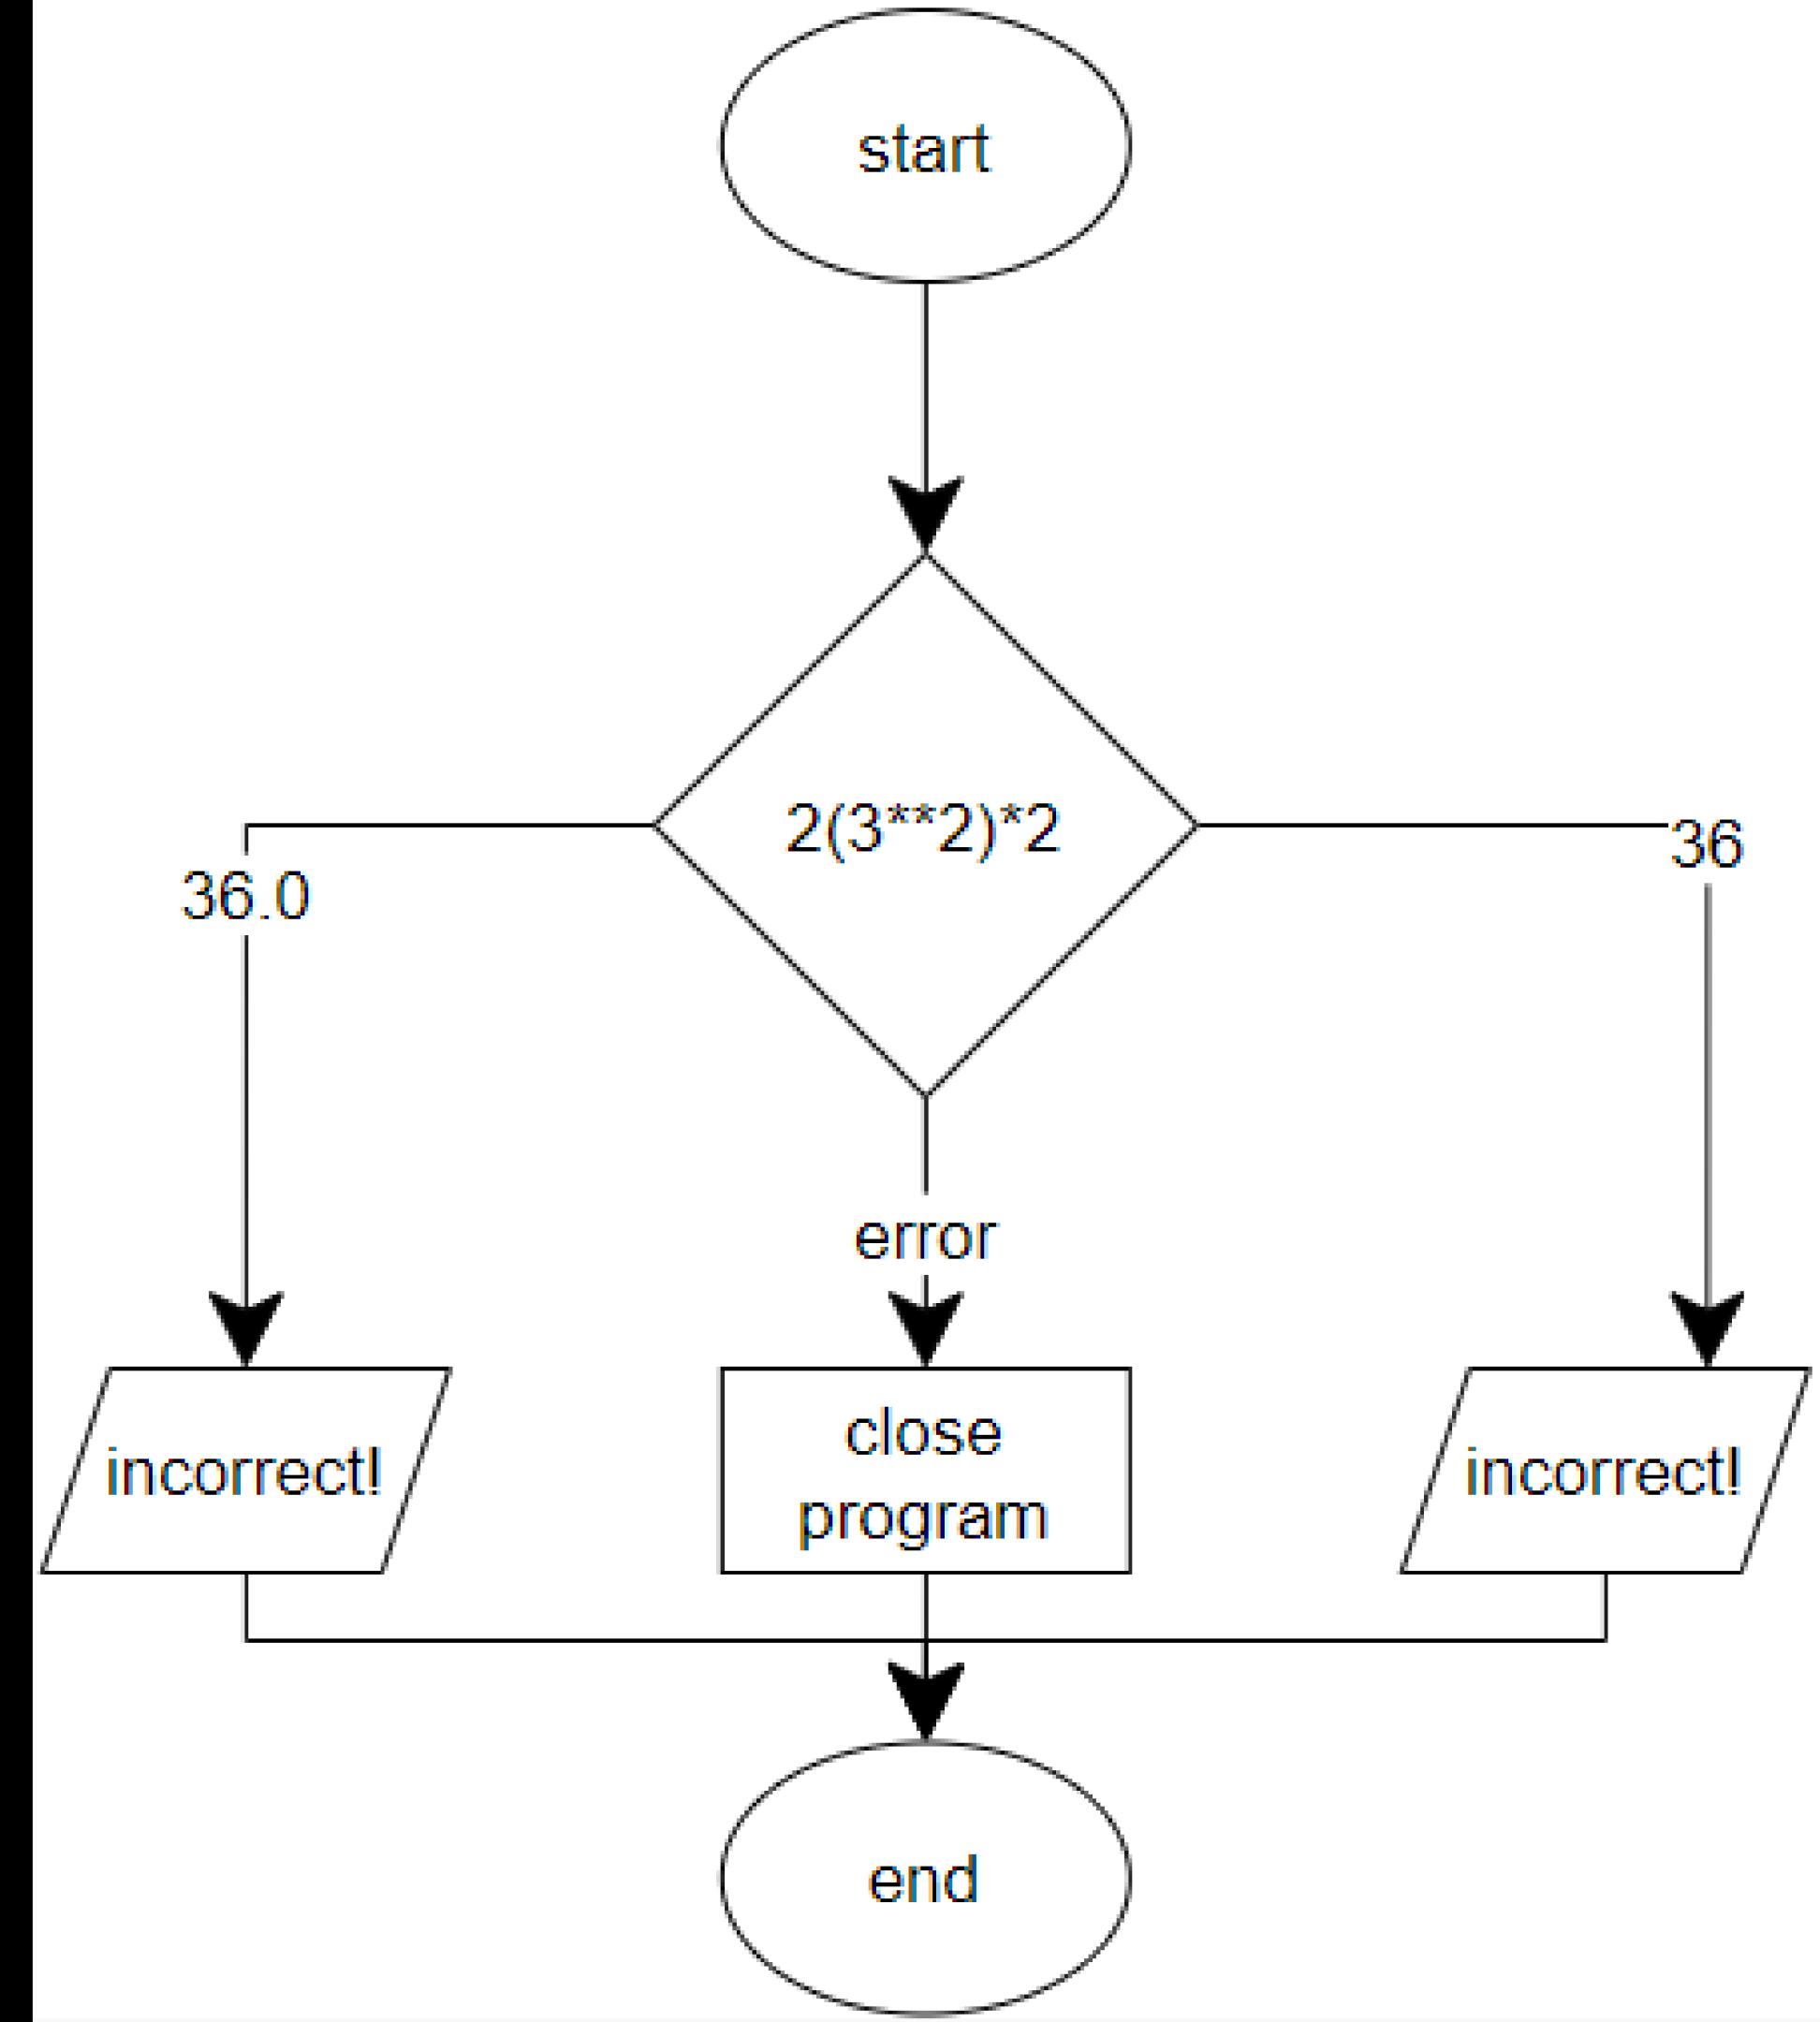

## 1.1 Conditions

## 1.1 Conditions

## 1.1 Conditions

# Boolean Algebra

- Introduced by the mathematician George Boole in the book "The Mathematical Analysis of Logic," and "An Investigation of the Laws of Thought"

# Boolean Algebra

- Boolean algebra's primary use has been in computer programming languages
- True or False
  - 1 or 0
  - deals with relational and logical operations

## 2.2 Recap on Prescedence

Precedence	Operator Sign	Operator Name
Highest	**	Exponentiation
	+X, -X, ~X	Unary positive, unary negative, bitwise negation
	*, /, //, %	Multiplication, division, floor, division, modulus
	+, -	Addition, subtraction
	<<, >>	Left-shift, right-shift
	&	Bitwise AND
	^	Bitwise XOR
		Bitwise OR
	==, !=, <, <=, >, >=, is, is not	Comparison, Identity
	not	Boolean NOT
	and	Boolean AND
Lowest	or	Boolean OR

# Boolean Algebra

- Usually, relational operators must come first before the logical operators
- Although bitwise logical operators defy this, we work around it via brackets

## 2.2 Recap on Prescedence

# Boolean Algebra

```
print (8==8) # True
```

```
print (9>=9) # True
```

```
print (8==8 and 9>=9) # True
```

# Boolean Algebra

True

True

True

- relational operators work to check variables, logical operators work to check truth values

# Boolean Algebra

```
print(True == 'True')
print(True != 'True')
print(1 > 11)
print(11 >= 12)
print(2**3/4*2 == 1.0)
print(1 == True and 0 == False)
print(1 == True ^ 0 == False)
```

## 2.2 Recap on Prescedence

Precedence	Operator Sign	Operator Name
Highest	$**$	Exponentiation
	$+x, -x, \sim x$	Unary positive, unary negative, bitwise negation
	$*, /, //, \%$	Multiplication, division, floor, division, modulus
	$+, -$	Addition, subtraction
	$<<, >>$	Left-shift, right-shift
	$\&$	Bitwise AND
	$\wedge$	Bitwise XOR
	$ $	Bitwise OR
	$==, !=, <, <=, >, >=, \text{is}, \text{is not}$	Comparison, Identity
	not	Boolean NOT
	and	Boolean AND
Lowest	or	Boolean OR

## 2.2 Recap on Prescedence

- Take note of the bitwise logical operations

False

True

False

False

False

True

False

## 2.2 Recap on Prescedence

# Boolean Algebra

- the main operations are conjunction, disjunction, and negation

# Conjunction

- Logical conjunction is an operation on two logical values, typically the values of two propositions, that produces a value of true if and only if both of its operands are true.

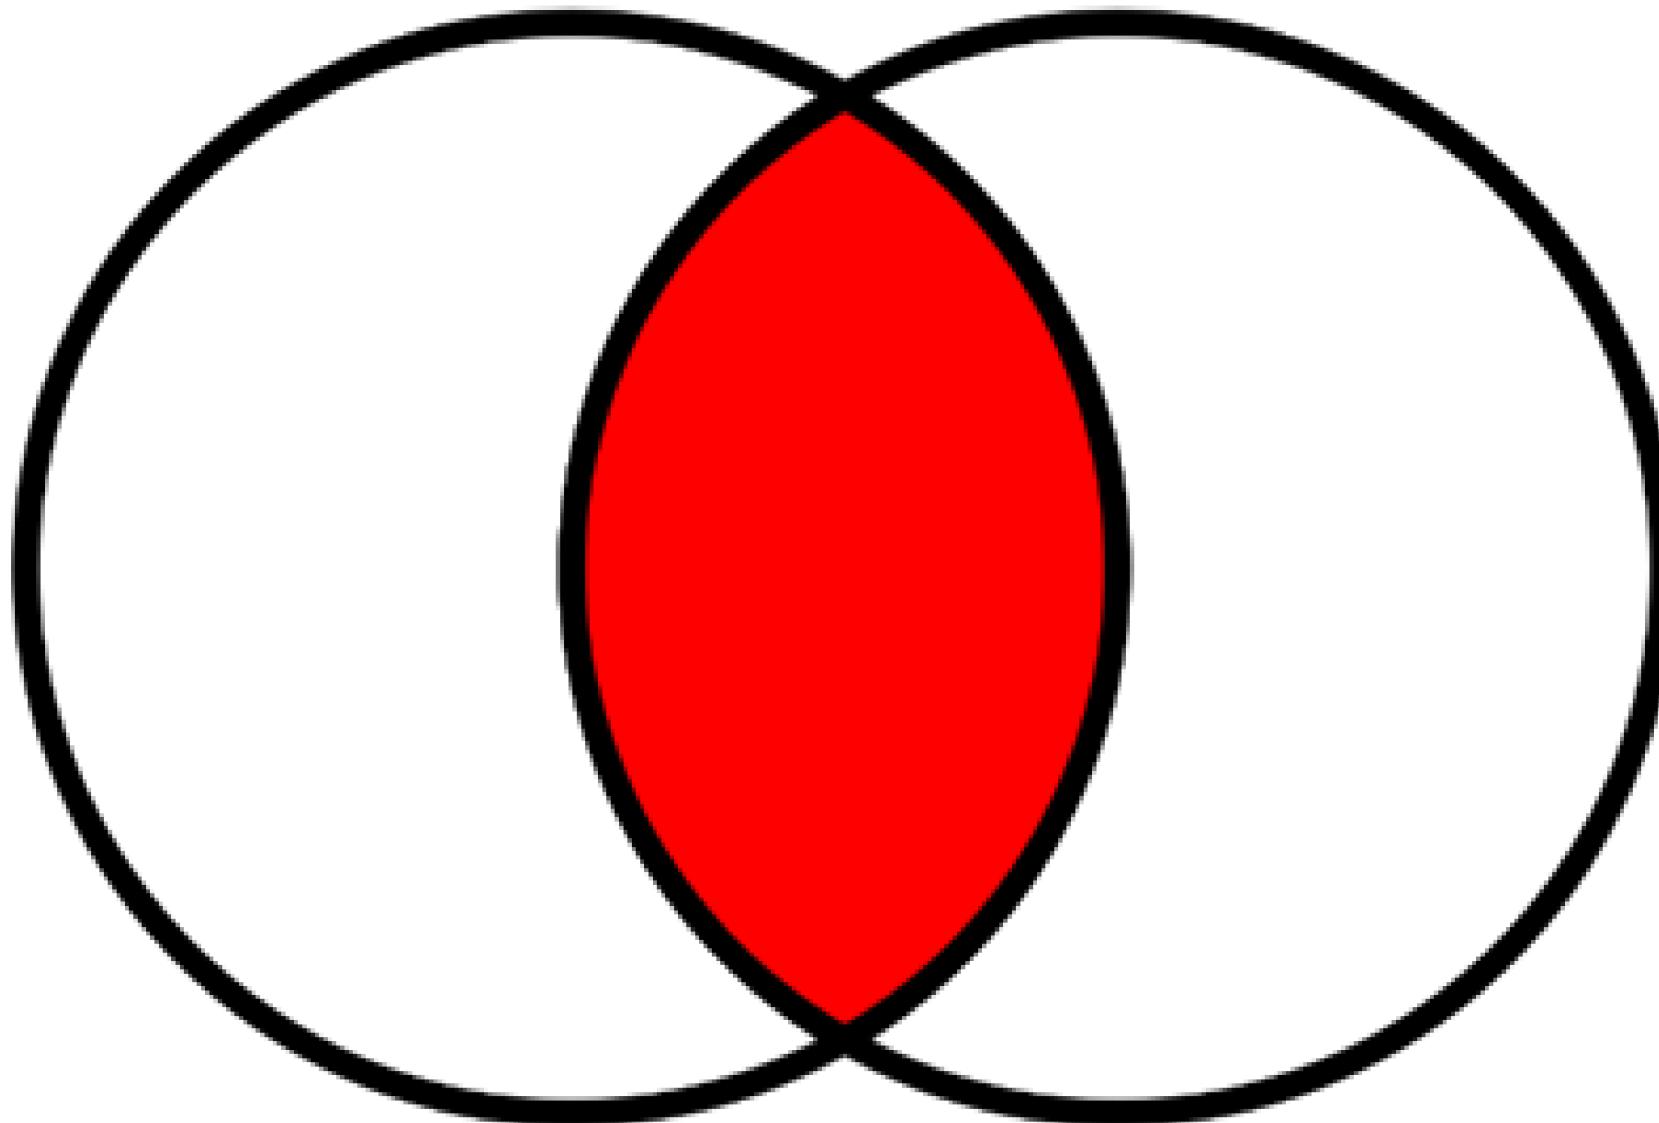

# Conjunction

- “True and True to be equal to True”
- may use relational operators, bitwise ampersand (&), or the keyword ‘and’

## 2.3 Conjunction

# Conjunction

# Conjunction

```
1 print(True and True)
2 print(False and True)
3 print(True and False)
4 print(False and False)
```

## 2.3 Conjunction

# Conjunction

True

False

False

False

## 2.3 Conjunction

# Conjunction

Logical 'and'				
L \ R	True	False	n	0
True	True	False	n	0
False	False	False	False	False
n	True	False	<u>nR</u>	0
0	0	0	0	0

## 2.4 Disjunction

# 2 Types

- Inclusive and Exclusive

# Inclusive

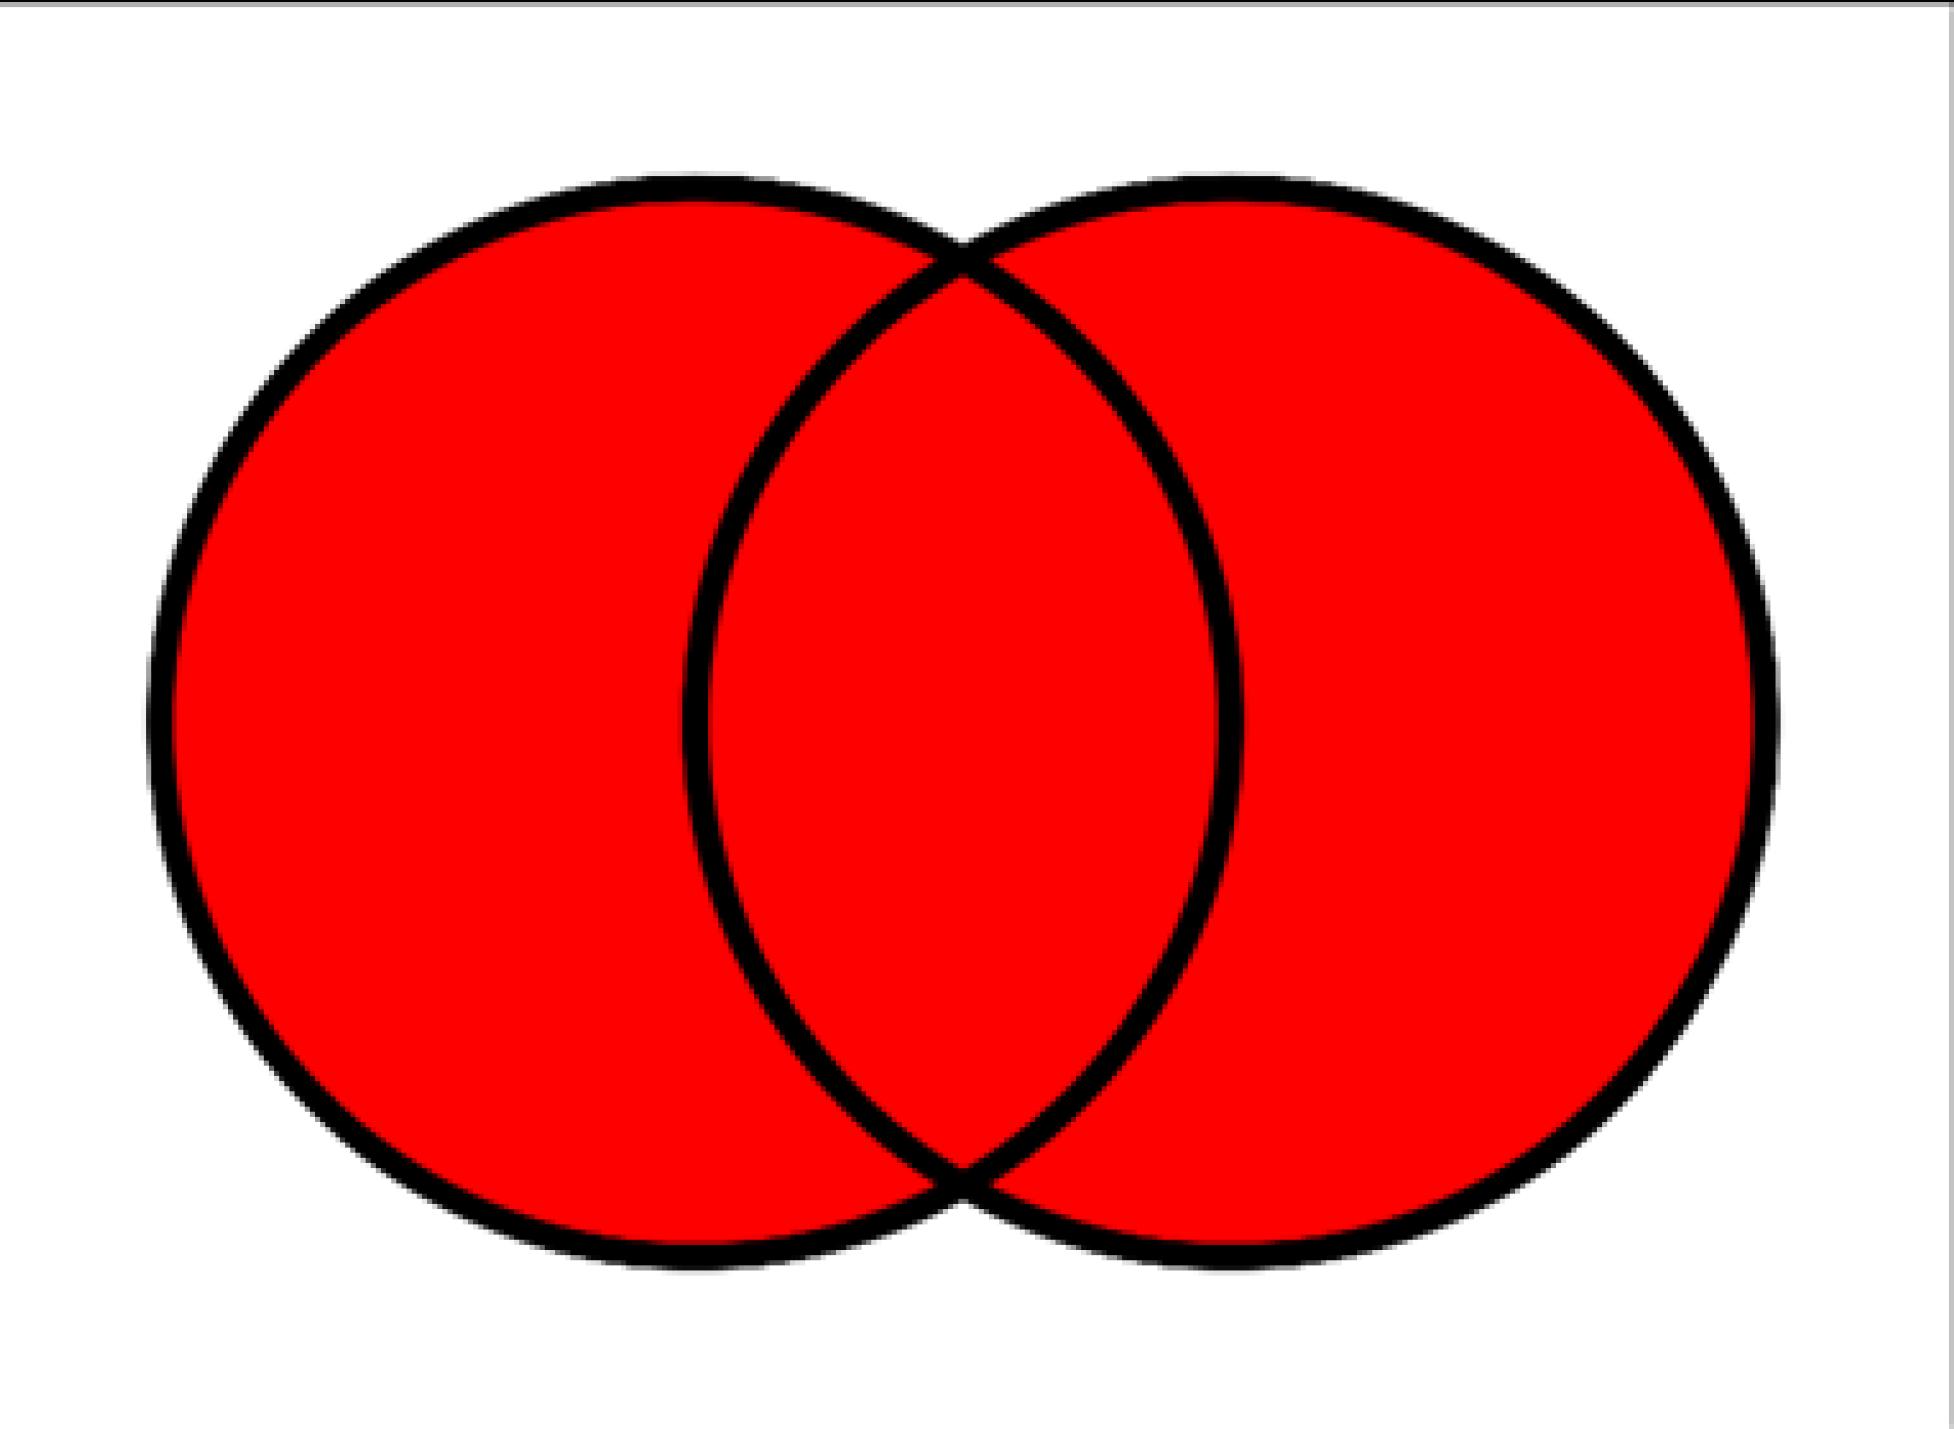

- A disjunction that remains true if either or both of its arguments are true
- Will still be true as long as at least one of the variables are True

# Inclusive

- Will only be False if both values are False
- may use relational operators, bitwise vertical bar(|), or the keyword 'or'

## 2.4 Disjunction

# Inclusive

## 2.4 Disjunction

# Inclusive

```
print(1==True or 1==1)
```

```
print(0!=True | 1==2)
```

```
print(1==True or 1==1 | 0!=True)
```

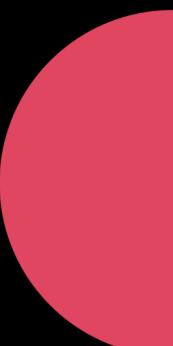

## 2.4 Disjunction

# Inclusive

True

False

True

## 2.4 Disjunction

# Inclusive

Logical 'or'				
L \ R	True	False	n	0
True	True	True	True	True
False	True	False	n	0
n	n	n	n <sub>L</sub>	n
0	True	False	n	0

# Exclusive

- A disjunction that is true if only one, but not both, of its arguments are true, and is false if neither or both are true, which is equivalent to the XOR connective

# Exclusive

- Will be true if only one variable is true

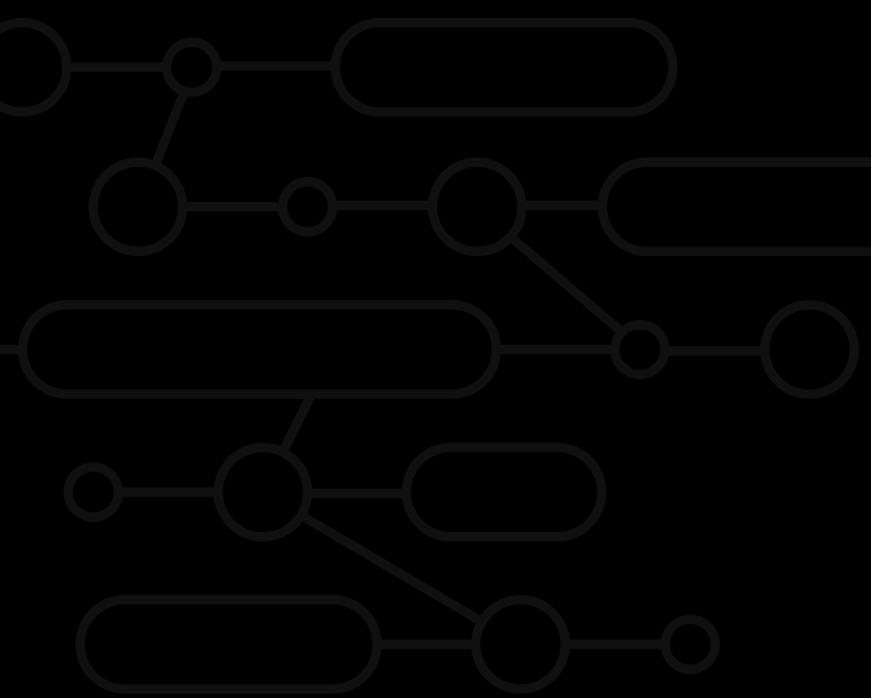

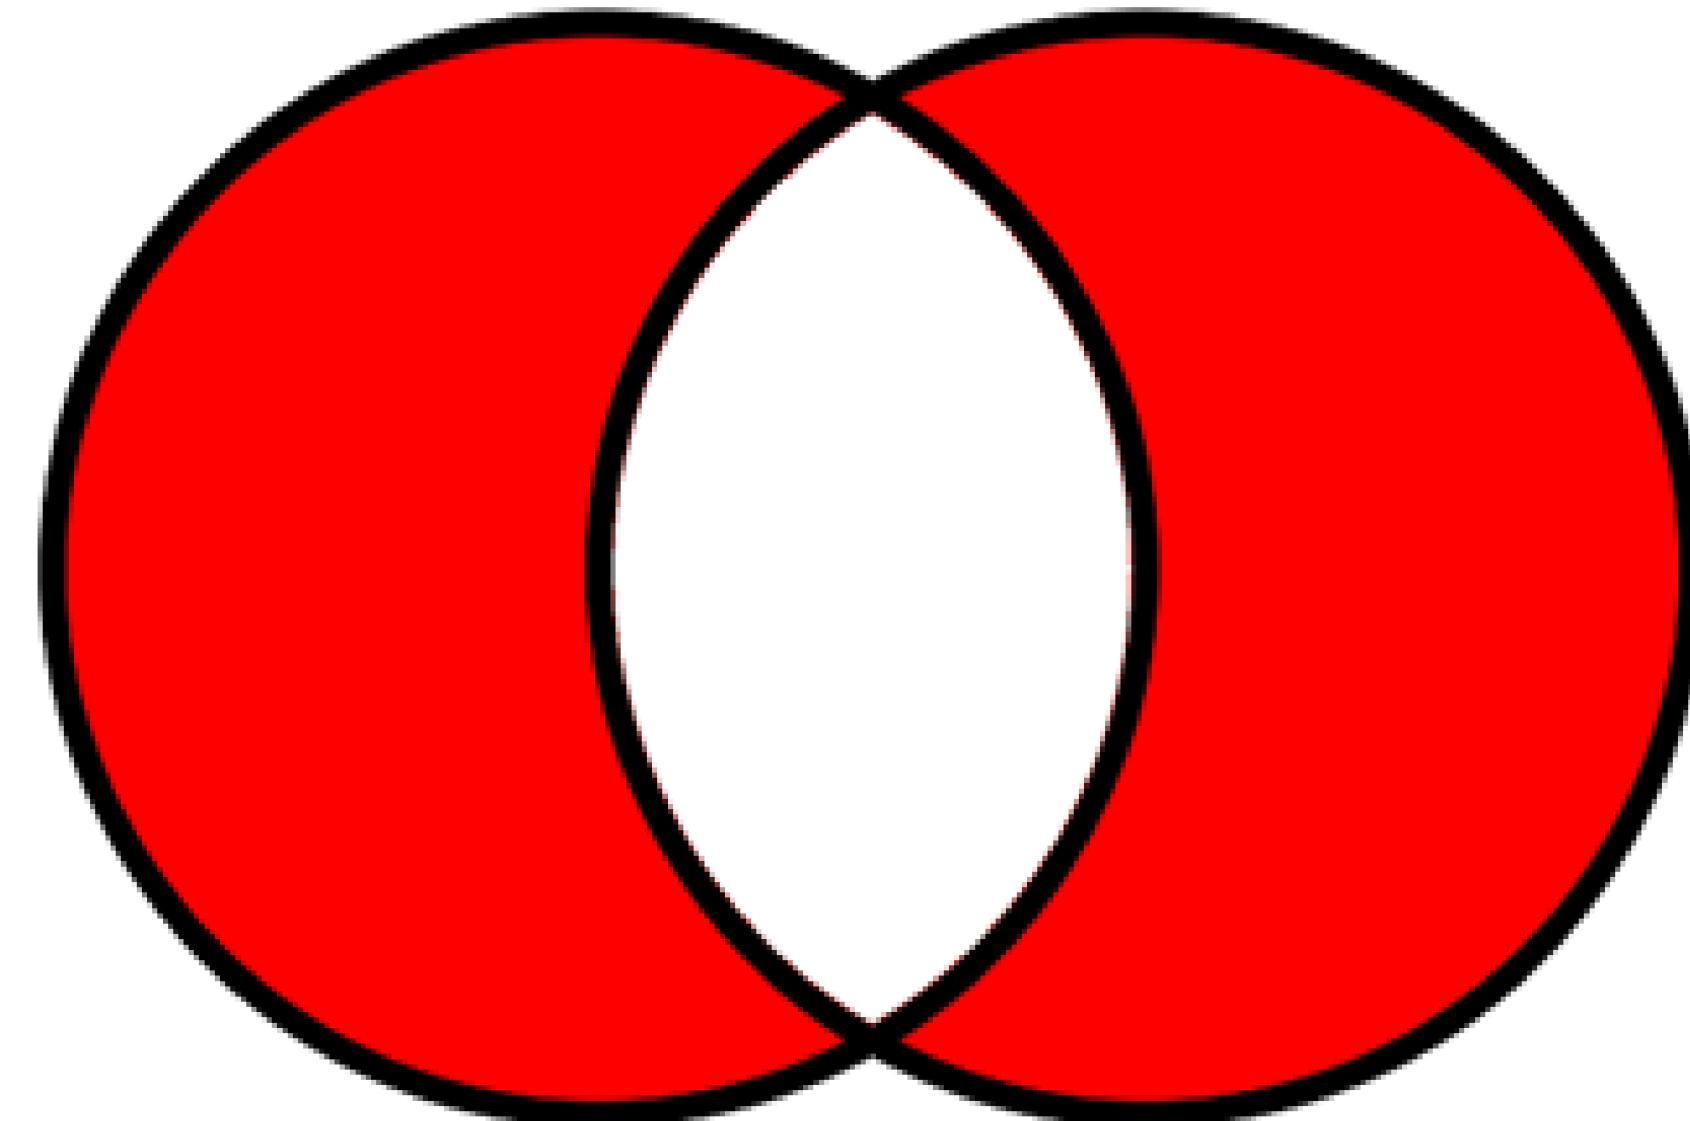

- Will be false if both variables are

True or if both variables are False

- may use relational operators,  
bitwise caret( $\wedge$ ) only

## 2.4 Disjunction

# Exclusive

# Exclusive

```
print(1==True ^ True==4)
print((1==True) ^ (True==4))
print(5>=5 ^ 6<7 and 3)
print(5>=5 ^ 6<7 or 8>1 and 3)
```

## 2.4 Disjunction

# Exclusive

False  
True  
3  
True

## 2.4 Disjunction

# Exclusive

Logical 'xor'

L \ R	True	False	n	0
True	False	True	(n-1)	(n-1)
False	True	False	n	0
n	(n-1)	n	(n-n)	n
0	1	0	n	0

# Negation

- Logical negation is an operation on one logical value that produces a value of true when its operand is false and a value of false when its operand is true

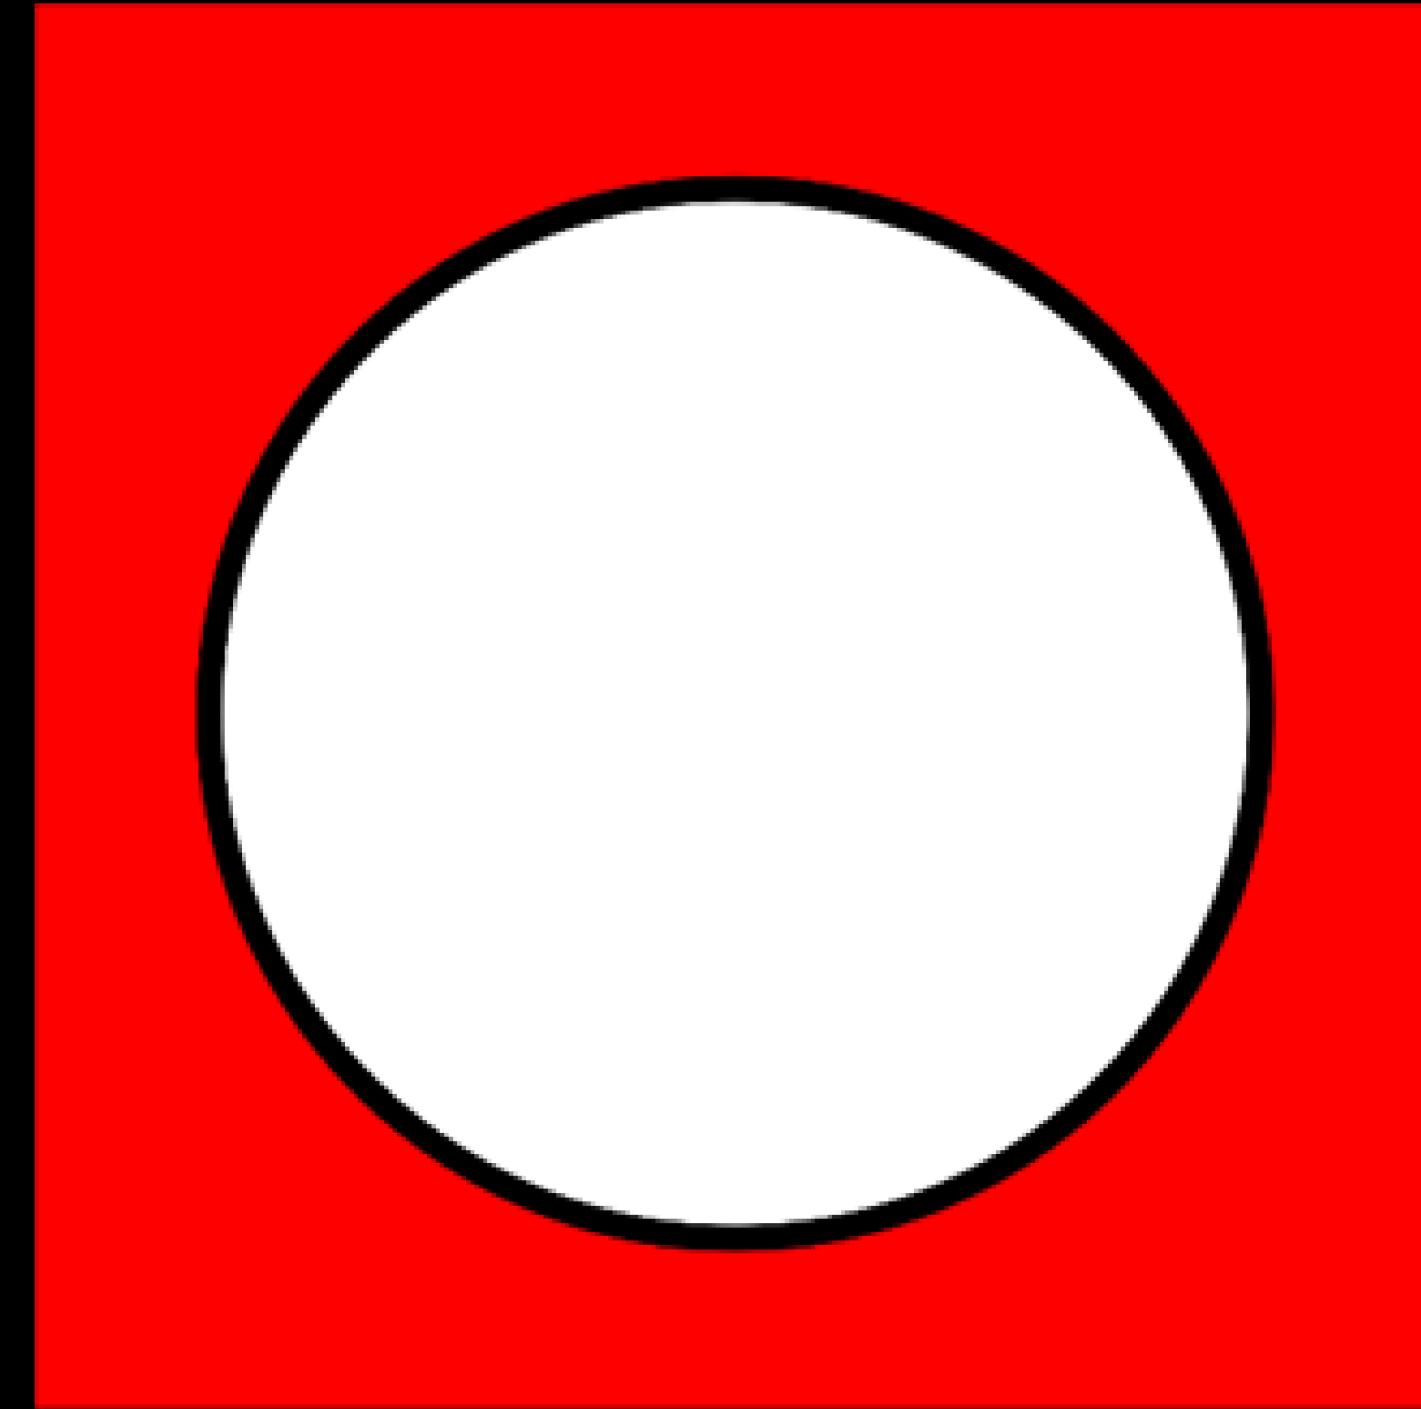

## 2.5 Negation

# Negation

- flips True to False and False to True
- uses the keyword ‘not’

## 2.5 Negation

# Negation

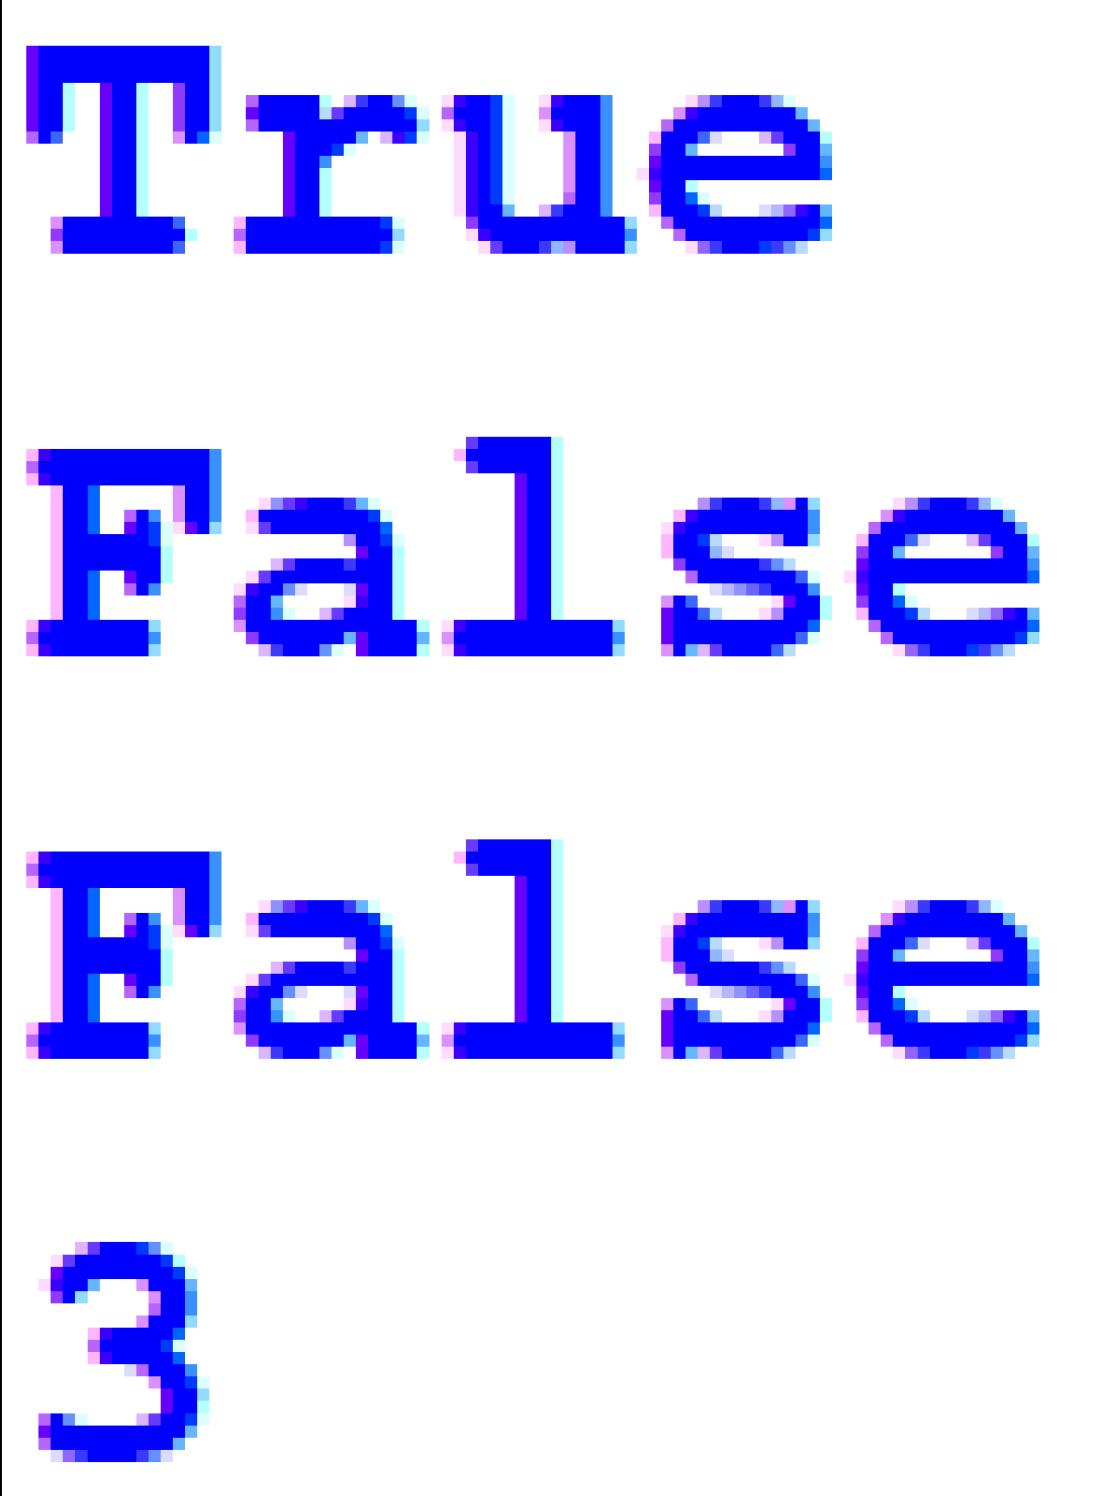

# Negation

```
print(not 1==True ^ True==4)
print(not((1==True) ^ (True==4)))
print(5>=5 ^ 6<7 and not 3)
print(not 5>=5 ^ 6<7 or 8>1 and 3)
```

## 2.5 Negation

# Negation

## 2.5 Negation

# Negation

Logical 'not'	
L\R	not
True	False
False	True
n	False
0	True

### 3.1 Definition

# Conditions

- Conditional expressions, involving keywords such as IF, ELIF, and ELSE, provide Python programs with the ability to perform different actions depending on a Boolean condition

### 3.2 'if' Statement

# 'if' Statement

- is one of the most used conditional statements in programming languages
- checks for a given condition, if the condition is True, then the set of code present inside the IF block will

### 3.2 'if' Statement

# 'if' Statement

- can be consecutive
- syntax:

```
if(<condition/s>):  
    <content>
```

### 3.2 'if' Statement

# 'if' Statement

```
1 x = 3
2
3 if x > 0:
4     print(x, 'is positive')
```

### 3.2 'if' Statement

# 'if' Statement

3 is positive

# 'if' Statement

```
1 x = 3
2
3 if x > 0:
4     print(x, 'is positive')
5 if x > 1:
6     print(x, 'is greater than 1')
7 if x > 2:
8     print(x, 'is greater than 2')
9 if x > 3:
10    print(x, 'is greater than 3')
```

### 3.2 'if' Statement

# 'if' Statement

3 is positive

3 is greater than 1

3 is greater than 2

### 3.2 'if' Statement

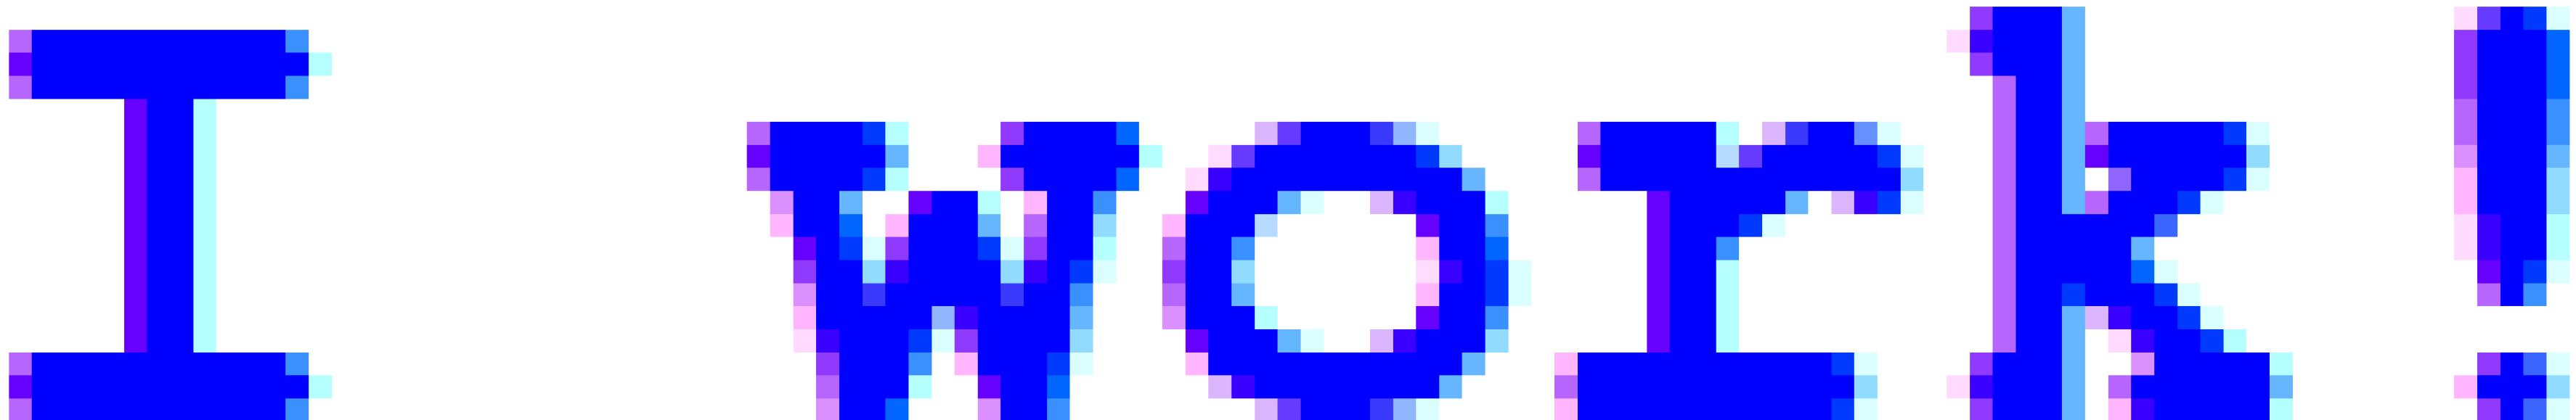

# 'if' Statement

```
1 x == 3
2
3 if x!=True ^ True!=3:
4     print('I work!')
```

### 3.2 'if' Statement

# 'if' Statement

### 3.3 'if ... else' Statement

# 'if ... else' Statement

- is used if none of the previous conditions are met
- is a 'fail-safe', will execute if conditions above are all False
  - is optional in a 'if-else' code block
  - 'else' Statement is optional

### 3.3 'if ... else' Statement

# 'if ... else' Statement

- syntax:

```
if(False):
```

```
    <content that will not run>
```

```
else:
```

```
    <content that will run>
```

### 3.3 'if ... else' Statement

# 'if ... else' Statement

```
x = 3
```

```
if x!=True ^ True==3:  
    print('I work!')  
  
else:  
    print("I don't work")
```

### 3.3 'if ... else' Statement

# 'if ... else' Statement

I do it twice

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

```
1 x = 3
2
3 if x > 0:
4     print(x, 'is positive')
5 if x > 3:
6     print(x, 'is greater than 3!')
7 else:
8     print(x, 'is less than 4!')
```

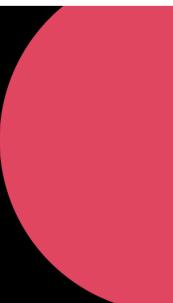

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

3 is positive

3 is less than 4!

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

- is used to check additional conditions if the first condition is evaluated as False

• 'else if'

- is used only under an 'if' statement and can have multiple 'elif' Statements

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

- syntax:

```
if(False):
```

```
    <content that will not be executed>
```

```
elif(<additional condition that might be True>):
```

```
    <content that might be executed>
```

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

```
1 x = 3
2
3 if x>0:
4     print('this is positive')
5 elif x==3:
6     print('this is 3')
7 else:
8     print('this is not a number')
```

### 3.4 'if ... elif' Statement

# 'if ... elif' Statement

this is positive

### 3.5 'if...elif...else' Statement

# 'if...elif...else' Statement

- note that there can only be one 'if' statement, one or multiple optional 'elif' statements, and an optional 'else' statement

### 3.5 'if...elif...else' Statement

# 'if...elif...else' Statement

- syntax:

```
if(<condition>):
    <content that might run>
<elif(<other condition>):
    <content that might run>
    >
<else:
    <content that might run>
    >
```

### 3.5 'if...elif...else' Statement

# 'if...elif...else' Statement

```
1 x = 3
2
3 if x > 0:
4     print(x, 'is positive')
5 elif x > 3:
6     print(x, 'is greater than 3!')
7 else:
8     print(x, 'is less than 4!')
```

### 3.5 'if...elif...else' Statement

# 'if...elif...else' Statement

3 is positive

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

- from version 3.10 upwards, Python has implemented a switch case feature called “structural pattern matching”.
- it works much like consecutive ‘if’ statements, will check one-by-one all ‘case’s even if a case has already been True

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

- it tries to see(match) if a variable 'is equal to' the following cases

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

- the optional underscore() symbol is used to denote “default”
  - imagine it like the ‘else’ statement

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

- syntax:

```
match <variable_name>:
```

```
    case <condition>:
```

```
        <content>
```

```
    case _:
```

```
        <content>
```

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

```
1 x = '3'  
2  
3 match x:  
4     case '3':  
5         print('this is 3')  
6     case _:  
7         print('this is not 3')
```

### 3.6 'Match-Case' Statement

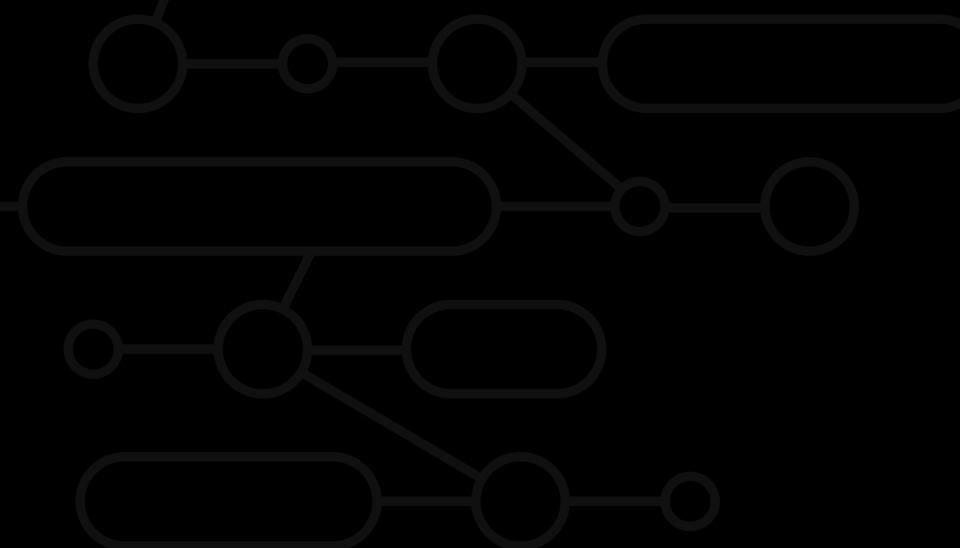

# 'Match-Case' Statement

is

is

3

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

```
1 x = 3
2
3 match x:
4     case '3':
5         print('this is 3')
6     case _:
7         print('this is not 3')
```

### 3.6 'Match-Case' Statement

# 'Match-Case' Statement

this is not 3

## 4.1 Nesting

# Nesting

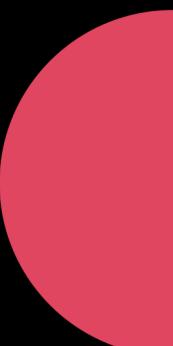

- code block structures like 'try-except' and 'if' statements create indentations below them to denote that the following lines are part of the code block

## 4.1 Nesting

# Nesting

- it is where code blocks fit in other code blocks, structures inside other structures

# Nesting

- if that is the case, can we put 'if' statements inside another 'if' statement? A 'match-case' inside an 'if' statement? An 'if' statement inside a 'match-case'?

# Nesting

```
1 x = 3
2
3 if x > 0:
4     print('this is positive')
5     if x < 4:
6         print('this is below 4')
7     else:
8         print("i don't know, sir")
9 else:
10    print('Happy Birthday!')
```

## 4.1 Nesting

## OBJECTIVES:

01

**Definition**

02

**Parts of a Loop**

03

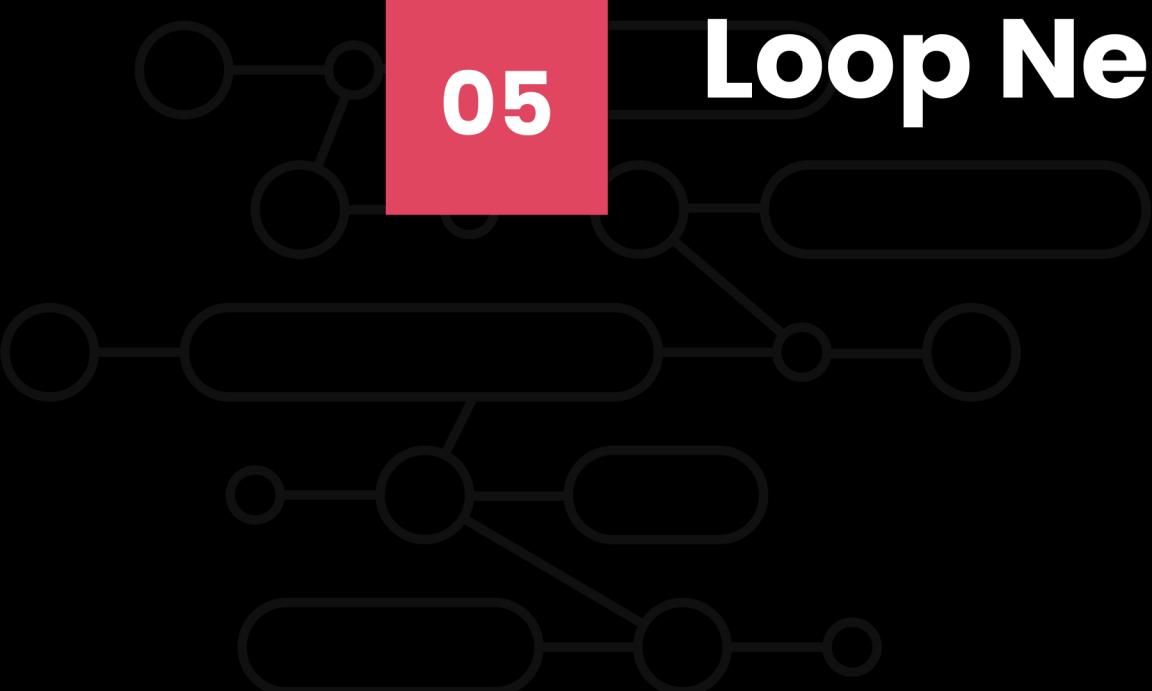

**Types of Loops**

04

**Repetition Structures in Python**

05

**Loop Nesting**

## 1.1 Definition

# Repetition

- the recurrence (duplication) of an action or event

# Repetition Control Structures

- repetition control structures are also referred to as iterative structures
- these are groups of code which are designed to repeat a set of statements

# Repetition Control Structures

- this repetition can repeat zero or more times, until some control value or condition causes the repetition to cease

## 1.1 Definition

# Loops

- most common term to describe repetition control structures

## 2.1 Parts of a Loop

# Declaration of 'counter' variable

- the creation of a variable that will be compared every time the body is executed at least once

## 2.1 Parts of a Loop

# Condition

- the logic that evaluates True or False
- if the condition is True, the loop will repeat
- if the condition is False, the loop will end and exit the structure

## 2.1 Parts of a Loop

# Body

- the code block/s within the loop

## 2.1 Parts of a Loop

# 'counter' Variable Update

- the change that happens to the 'count' variable if the condition is true
- can use arithmetic operators, direct assignment via a conditional structure, or special keywords

### 3.1 Types of Loops

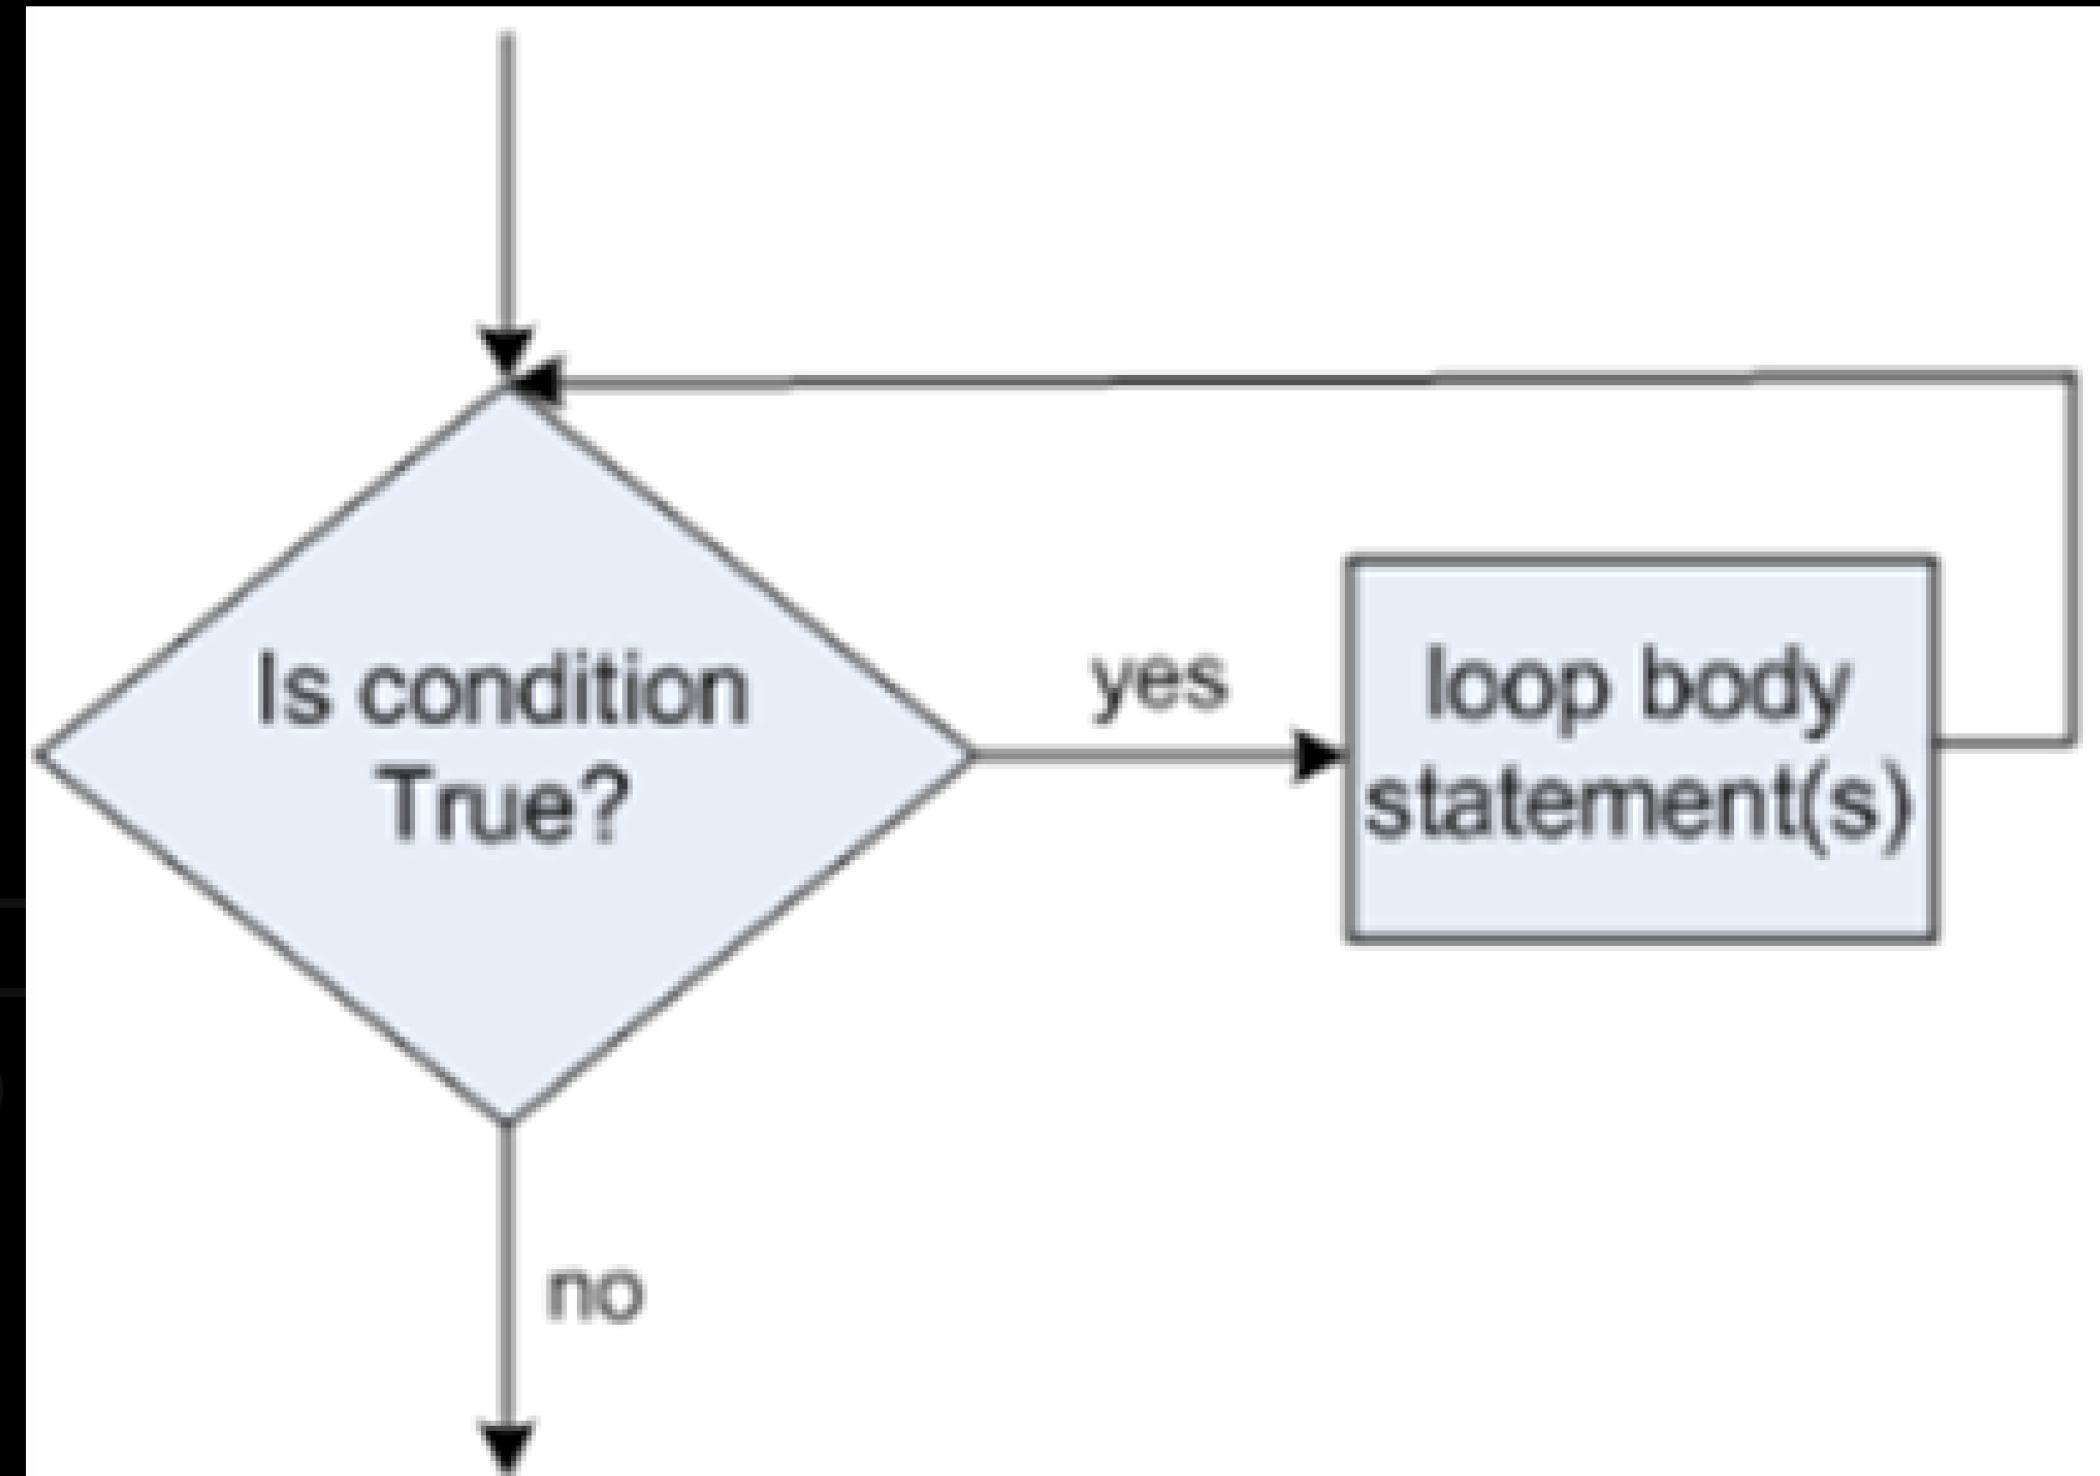

## Pre-test

- can execute its body a minimum of zero times, if the initial condition evaluates to

False

### 3.1 Types of Loops

## Pre-test

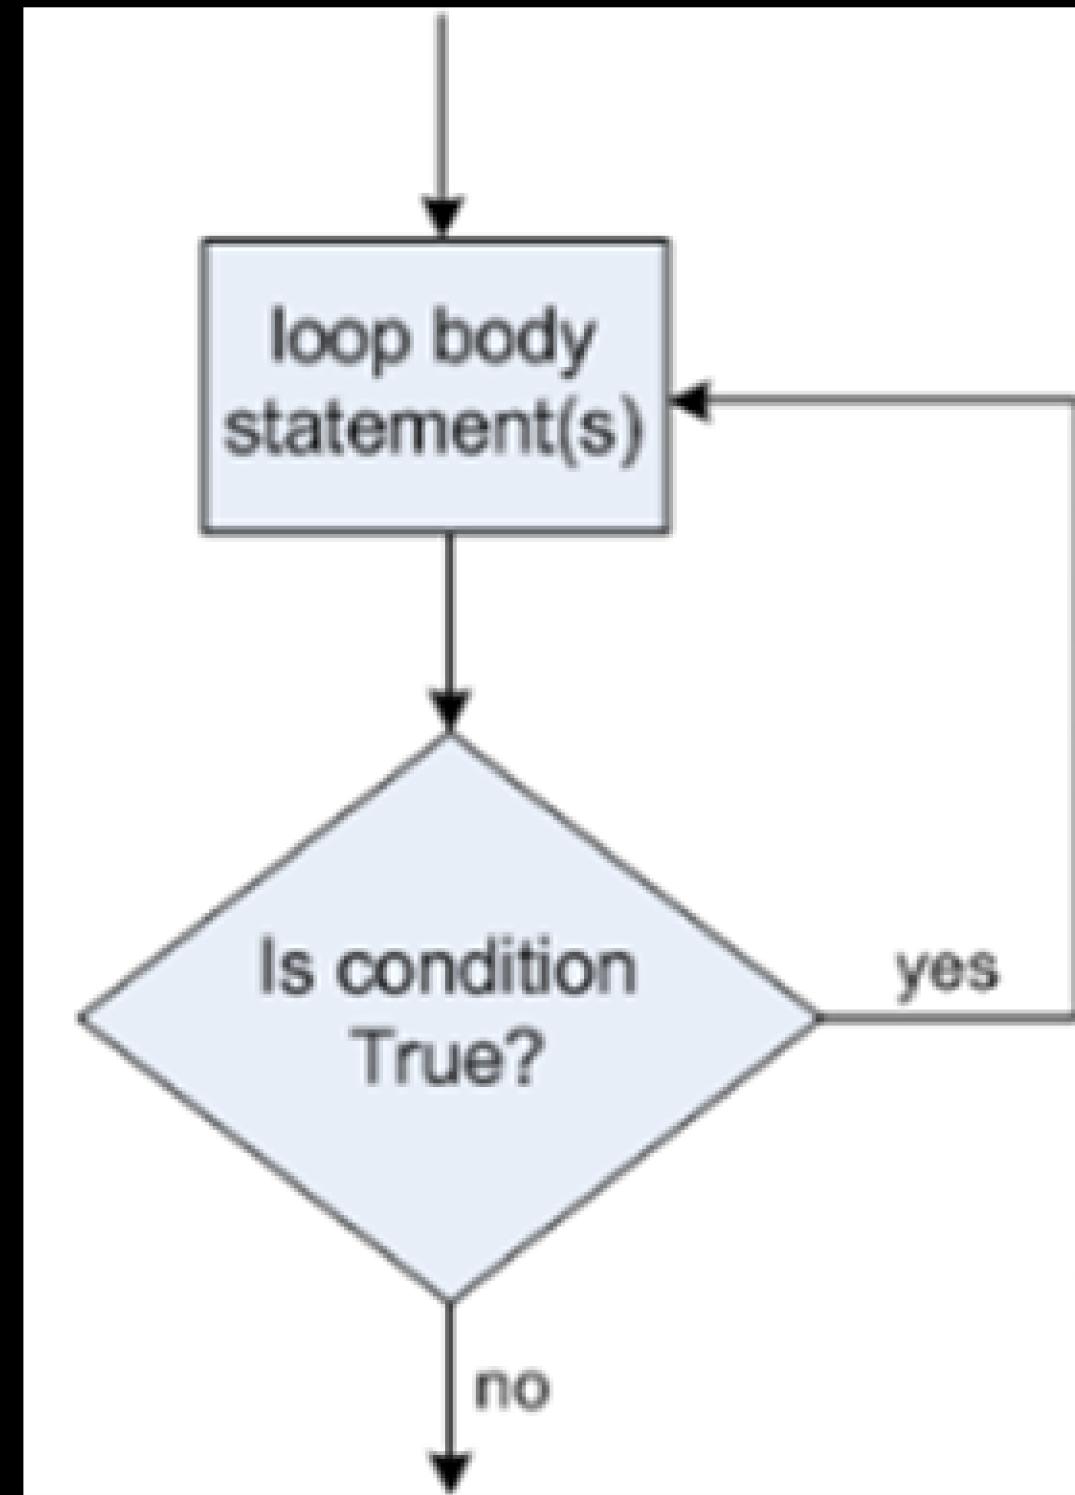

### 3.1 Types of Loops

## Post-test

- can execute its body a minimum of one time even if the initial condition evaluates to False

### 3.1 Types of Loops

# Post-test

### 3.1 Types of Loops

## Post-test

- Python does not have a Post-test loop but an example is Java's 'do-while' Loop

## 4.1 Types of Loops

# 'while' Loops

- is a statement in Python that repeatedly executes a block of statements if a test at the top keeps being True

## 4.1 Types of Loops

# 'while' Loops

- when the test in the 'while' condition becomes False, the process continues to the statement that is below the 'while' block

## 4.1 Types of Loops

# 'while' Loops syntax

<'counter' Variable Update>

while(<condition>)

<body>

<'counter' Variable Update >

## 4.1 Types of Loops

# 'while' Loops syntax

```
1 i = 0
2
3 while i < 5:
4     print("Hello!")
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'break' Keyword
  - stops the loop, exits the structure
  - used only inside the loop

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'break' Keyword

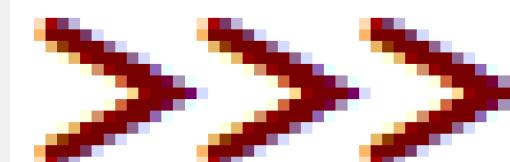

```
1 while True:  
2     response=input("color?")  
3     if response=="blue":  
4         break
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'break' Keyword

```
color?red  
color?purple  
color?blue
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'continue' Keyword
  - goes directly to the top, checking the condition and will execute code again if condition is False
  - used only inside the loop

# 'while' Loops Optional Keywords

- 'continue' Keyword

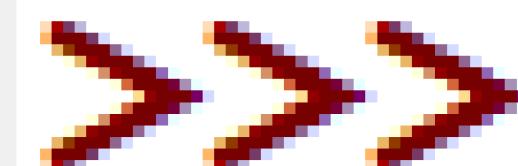

```
1 while True:  
2     response=input("color?")  
3     if response=="blue":  
4         break  
5     else:  
6         continue  
7     print("I am ignored")
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'continue' Keyword

```
color?red  
color?purple  
color?blue
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'else' Keyword
  - this runs if and only if the loop is exited, exited by not triggering a 'break' Keyword
  - is used outside the loop indentation

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'else' Keyword

```
1 i = 0
2 while i<3:
3     response=input("color?")
4     if response=="blue":
5         break
6     i += 1
7 else:
8     print("successful 3 iterations")
```

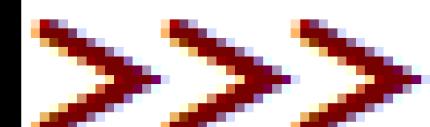

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'else' Keyword

```
color?red  
color?purple  
color?green  
successful 3 iterations
```

color?blue

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'pass' Keyword
  - literally, does nothing but is used as a substitute to occupy code blocks that require content

# 'while' Loops Optional Keywords

- 'pass' Keyword

```
1 i = 0
2 while i<3:
3     response=input("color?")
4     if response=="blue":
5         pass
6     else:
7         print("this is not blue!")
8     i += 1
```

## 4.1 Types of Loops

# 'while' Loops Optional Keywords

- 'pass' Keyword

```
color?red  
this is not blue!  
color?green  
this is not blue!  
color?purple  
this is not blue!
```

>>>

```
color?blue  
color?blue  
color?blue
```

>>>

## 4.1 Types of Loops

# 'for' Loops

- usually used to go through sequence structures
- also uses optional keywords 'break', 'continue', 'else', 'pass'
- automatically increments the counter variable

## 4.1 Types of Loops

# 'for' Loops syntax

```
for <any_other_var_name> in <structure>:  
    <content>
```

## 4.1 Types of Loops

# 'for' Loops syntax

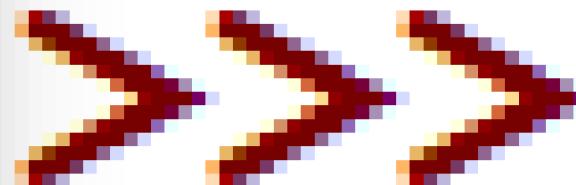

```
1 my_list = [1, 2, 3, 4, 5]
2
3 for i in my_list:
4     if i == 2:
5         print("I found the one")
6         break
7     else:
8         print("still looking...")
```

## 4.1 Types of Loops

# 'for' Loops syntax

still looking...  
I found the one

## 5.1 Loop Nesting

# Loop Nesting

- can use 'for' and 'while' Loops
- much like nested 'if' statements, there can be loops inside other loops

## 5.1 Loop Nesting

# Loop Nesting

- there can be a ‘while’ Loop inside a ‘while’ Loop, a ‘for’ Loop inside a ‘for’ Loop, a ‘for’ Loop inside a ‘while’ Loop, a ‘while’ Loop inside a ‘for’ Loop and so on and so forth.
- take note of indentations, they make a difference between consecutive loops instead of nested loops and vice versa.

# Loop Nesting

```
1 my_list = [1, 2, 3, 4, 5]
2
3 i=0
4
5 while i < len(my_list):
6     if my_list[i] % 2 == 0:
7         print(my_list[i], "is even")
8     else:
9         print(my_list[i], "is not even")
10    for x in my_list:
11        print(my_list[i])
12    i=i+1
```

- How many are the methods?

# Functions vs. Methods

- A function is a set of instructions or procedures to perform a specific task
- A method is a set of instructions that are associated with an object.

## 2.1 Built-in Functions

# Built-in Functions

- functions that are part of the 'libraries' you downloaded when you started to program in that language

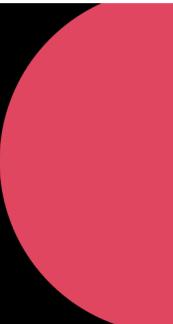

## 2.1 Built-in Functions

# Built-in Functions

```
System.out.println("Hello World");
```

```
print("Hello World")
```

### 3.1 User-defined Functions

# User-defined Functions

- take note to not use keywords to name your user-defined functions

### 3.1 User-defined Functions

# User-defined Functions Syntax

- In Python, create as:

```
def <function_name>(<parameters>):  
    <content>
```

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
def hello_world():
    print("Hello World")
```

### 3.1 User-defined Functions

# User-defined Functions Syntax

- In Python, refer as :

`<function_name>(<arguments>)`

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
def hello_world():
    print("Hello World")
```

```
hello_world()
```

## 3.1 User-defined Functions

# User-defined Functions Syntax

A horizontal row of five 8x8 pixel grayscale images. From left to right, they show handwritten digits: 'T', 'M', 'P', 'J', and 'd'. Each digit is drawn in black on a white background, with some noise or variations in stroke thickness.

# Arguments vs. Parameters

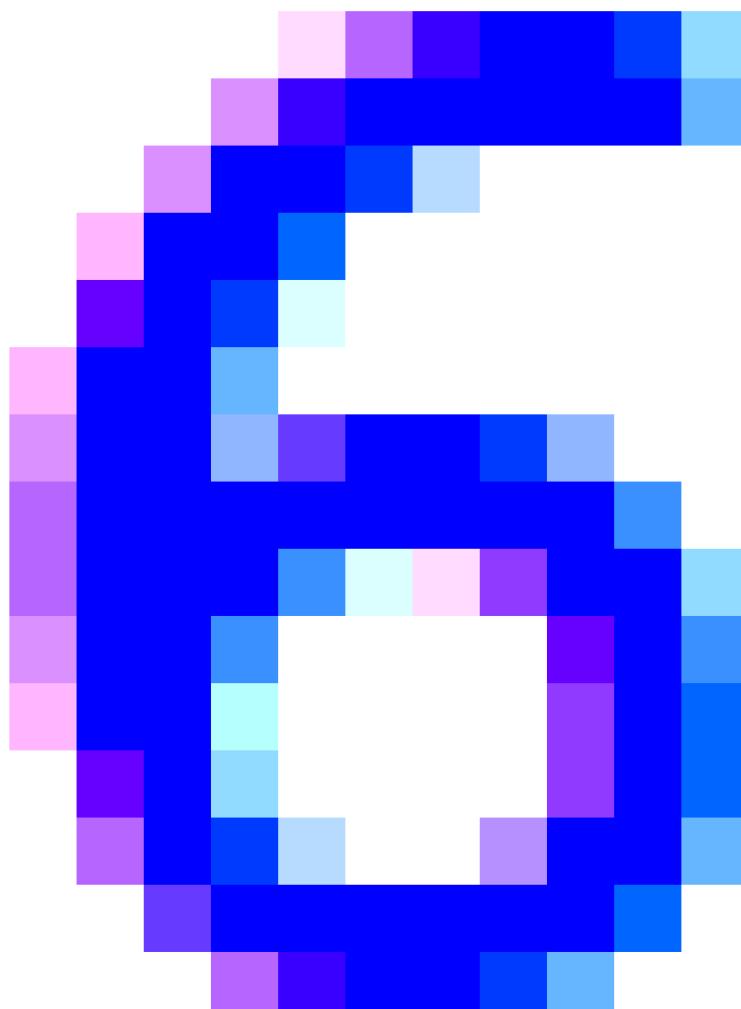

- arguments are values put inside the parentheses when referring to a function
- parameters are the variables put inside the parentheses when creating a function

# Arguments vs. Parameters

```
1 def multiply(x, y):  
2     return x*y  
3  
4 a = 2  
5 b = 3  
6 print(multiply(a, b))
```

### 3.1 User-defined Functions

# Arguments vs. Parameters

## Return

- refers to what the function will give back as a value when the function is used
- is optional, uses the 'return' Keyword
- unlike other languages, you do not need to explicitly declare a return type of the function in Python

### 3.1 User-defined Functions

# Functions with an Arbitrary Number of Arguments

- sometimes, there may not be argument that will be passed to the function
  - in Python, we use the '\*' symbol as a prefix

# Functions with an Arbitrary Number of Arguments

```
1 def multi_args(*args):  
2     for i in args:  
3         print(i)
```

### 3.1 User-defined Functions

# Functions with an Arbitrary Number of Arguments

- we can pass primitives and non-primitive values

### 3.1 User-defined Functions

## Functions with an Arbitrary Number of Arguments

```
1 def multi_args(*args):  
2     for i in args:  
3         print(i)  
4  
5  
6 sample_list = [5, 8, 10, 12, 15]  
7 multi_args(sample_list)  
8 multi_args(*sample_list)
```

### 3.1 User-defined Functions

## Functions with an Arbitrary Number of Arguments

```
[5, 8, 10, 12, 15]
```

5

8

10

12

15

### 3.1 User-defined Functions

## Functions with an Arbitrary Number of Arguments

- when passing mutable structures, take note:
- Mutating a parameter will mutate the argument
- reassigning the parameter won't reassign the argument

### 3.1 User-defined Functions

## Functions with an Arbitrary Number of Arguments

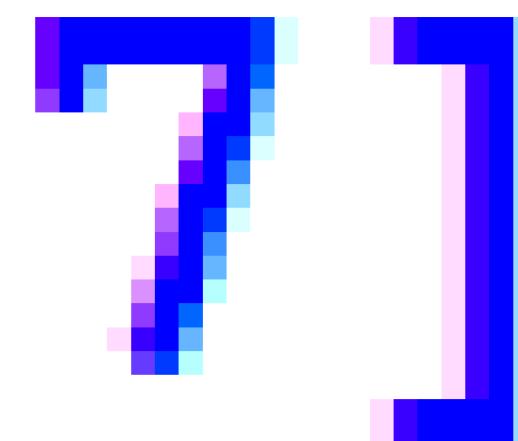

```
1 def sample(x):
2     x[0] = 10
3     x = [20, 30, 40]
4     x[1] = 15
5     print(x)
6
7 y = [5, 6, 7]
8 sample(y)
9 print(y)
```

### 3.1 User-defined Functions

## Functions with an Arbitrary Number of Arguments

```
[20] 15 40]
```

```
[10] 6 ]
```

### 3.1 User-defined Functions

# User-defined Functions Syntax

- In Java, create as:

```
<access_modifier> <static> <return_type><method name>([parameters]){

    <method body>
```

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
<access_modifier> <static> <return_type><method name>([parameters]){\n    <method body>\n}
```

- access modifier
  - either public or private
  - by default is public

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
<access_modifier> <static> <return_type><method name>([parameters]){\n    <method body>\n}
```

- static
  - will determine if the method is 'static' or an 'instance' method

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
<access_modifier> <static> <return_type><method name>([parameters]){\n    <method body>\n}
```

- return type
  - refers to what the function will give back as a value when called
  - uses the 'return' keyword if it uses a data type

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
public static void main(String args[]) {  
    System.out.println("Hello Wrold");  
}
```

### 3.1 User-defined Functions

# User-defined Functions Syntax

```
1 package com.mycompany.demonstration;
